Abstract

The asynchronous π -calculus is considered the basis of experimental programming languages (or proposal of programming languages) like Pict, Join, and TyCO. However, at a closer inspection, these languages are based on an even simpler calculus, called *Localised π* ($L\pi$), where: (a) only the *output capability* of names may be transmitted; (b) there is no *matching* or similar constructs for testing equality between names.

We study the basic operational and algebraic theory of $L\pi$. We focus on bisimulation-based behavioural equivalences, precisely on *barbed congruence*. We prove two coinductive characterisations of barbed congruence in $L\pi$, and some basic algebraic laws. We then show applications of this theory, including: the derivability of the *delayed input*; the correctness of an optimisation of the encoding of call-by-name λ -calculus; the validity of some laws for Join; the soundness of Thielecke's axiomatic semantics of the *Continuation Passing Style calculus*.

*An extended abstract has appeared in the *Proceedings of 25th International Colloquium on Automata, Languages and Programming*, volume 1443, of *Lecture Notes in Computer Science*, Springer Verlag, July 1998.

1 Introduction

The *asynchronous π -calculus*, abbreviated π_a , is a variant of the π -calculus, where message emission is non-blocking. Formally, the output prefix $\bar{a}b.P$ of the π -calculus is replaced with the simpler output particle $\bar{a}b$, which has no continuation. The asynchronous π -calculus has been introduced by Honda and Tokoro [21], and independently Boudol [10], who showed that it is expressive enough to encode the (synchronous) π -calculus. Asynchronous communications are interesting from the point of view of concurrent and distributed programming languages, because they are easier to implement and they are closer to the communication primitives offered by available distributed systems.

The asynchronous π -calculus is considered the basis of experimental concurrent and/or distributed programming languages (or proposal of programming languages) like Pict [44], Join [15], and TyCO [59]. However, at a closer inspection, the programming languages above are based on an even simpler calculus, where:

- (a) the recipient of a name may only use it in output actions; that is, only the *output capability* of names may be transmitted;
- (b) there is no *matching* construct (or similar constructs like mismatching) for testing equality between channel names.¹

These restrictions are explicit in Join. In Pict and TyCO, (b) is explicit; (a) is not, but most programs comply with it. We call *Localised π* , abbreviated $L\pi$, the asynchronous π -calculus with the additional simplifications (a) and (b).

By restriction (a), the recipients of a channel are *local* to the process that has created the channel. More precisely, in a process $(\nu a)P$ the inputs at channel a are statically determined: no further inputs at a may be created, inside or outside P . For instance, the process

$$(\nu a)(\bar{b}a.P \mid a(x).Q \mid b(z).z(y).R$$

is not in $L\pi$ because, after a reduction along b , a new input at a is created. *Locality* of channels makes $L\pi$ particularly suitable for giving semantics to, and reasoning about, concurrent or distributed object-oriented languages. For instance, locality can guarantee the fundamental property that an object has unique identity. In object-oriented languages, the name a of an object may be transmitted; the recipient may use a to access its methods, but it cannot create a new object called a . When representing objects in the π -calculus, this usually translates into the constraint that the process receiving the object name may only use it in output [60, 25, 51, 26, 42, 53, 30].

Restriction (b), that is the *absence of matching*, is an important requirement too. Indeed, name-testing, like testing equality between pointers in imperative languages, prevents many useful program optimisations and transformations. Also from a programming point of view, the usefulness of matching is questionable. For instance, Join, Pict, and TyCO do not provide any construct for testing channels.

In this paper, we study the operational and algebraic theory of $L\pi$. We focus on bisimulation-based behavioural equivalences, and more precisely on *barbed congruence* [37]. Barbed congruence equates processes that, very roughly, in all contexts give rise to the same set of *observable actions*. Like other contextually-defined forms of bisimulation, barbed congruence is sensitive to the set of operators of a calculus. $L\pi$ is a sub-calculus of π_a and π -calculus, and therefore has fewer contexts. This allows us to gain useful process equalities. In this respect, the most important algebraic law of asynchronous π that is not in the theory of the synchronous π -calculus is the *asynchrony law*:

$$a(x).\bar{a}x = \mathbf{0}.$$

The asynchrony law essentially says that inputs can not be observed in π_a . Although this law is useful (it is used for instance by Nestmann and Pierce to prove the correctness of an encoding of

¹We may also view (b) as a consequence of (a), since testing the identity of a name requires more than the output capability.

guarded choice [38]), it seems fair to say that the restriction to asynchronous contexts does not allow us to gain much.

By contrast, asynchrony has strong semantic consequences under simplifications (a) and (b). Consider the following laws which are valid (under the specified conditions) in $L\pi$, but are false in π_a and in π -calculus:

$$\bar{a}b = (\nu c)(\bar{a}c \mid !c(x).\bar{b}x) \quad (1)$$

$$(\nu a)(!a(x).R \mid P \mid Q) = (\nu a)(!a(x).R \mid P) \mid (\nu a)(!a(x).R \mid Q) \quad (2)$$

$$(\nu a)(!a(x).R \mid C[\bar{a}b]) = (\nu a)(!a(x).R \mid C[R\{b/x\}]) \quad (3)$$

$$(\nu c)(\bar{a}c) = (\nu c)(\bar{a}c \mid c(x).\mathbf{0}) \quad (4)$$

$$(\nu c)(\bar{a}c) = (\nu c)(\bar{a}c \mid \bar{c}b) \quad (5)$$

Law 1, where $c \neq b$, equates processes that may perform syntactically different outputs: the process on the left performs the output of a global name b , whereas that on the right the output of a private name c . The forwarder process $!c(x).\bar{b}x$ makes the two processes indistinguishable. Law 2 is a distributivity law for replicated resources known as one of Milner's *replication theorems* [31]. This law is true in the π -calculus, under the hypothesis that name a is never transmitted and never used in input by processes P, Q and R . In $L\pi$, Law 2 is still valid when name a is transmitted by P, Q or R to the environment. Law 3 is reminiscent of *inline expansion*, an optimisation technique for functional languages which replaces a function call (the particle $\bar{a}b$) with an instance of the function body (the process $R\{b/x\}$). This law holds in $L\pi$ provided that name a does not appear free in input in process R and context $C[\cdot]$. (Also, by α -conversion we assume that all bound names are different from each other.) Finally, Laws 4 and 5 represent two forms of garbage collection. Notice that, in both laws, after the initial output, the derivatives are very different.

The main difficulty when proving that two processes are barbed congruent is represented by the quantification over contexts in the definition of barbed congruence. This quantification makes very hard to prove process equalities, and makes mechanical checking impossible. Simpler proof techniques are based on *labelled bisimulations* whose definitions do not use context quantification. These bisimulations should imply, or (better) coincide with, barbed congruence. In π -calculus barbed congruence coincides with the closure under substitutions of *synchronous early bisimilarity* [46]. Similarly, in π_a barbed congruence coincides with the closure under substitutions of *asynchronous early bisimilarity* [3]. In these proofs, a central role is played by the *matching* construct, for testing equality between names. If matching is removed from the language, then (the closure under substitutions of) early bisimilarity still implies barbed congruence, but the vice versa does not hold. Both characterisations are given on the class of the *image-finite* processes and exploit the n -approximants of the labelled equivalences.

In this paper, we give two characterisations of barbed congruence in $L\pi$ (as usual, on image-finite processes). The first is based on an embedding of $L\pi$ into a subcalculus where all names emitted are private. Barbed congruence between processes of $L\pi$ coincides, on their images, with (a slight variant of) *asynchronous ground bisimilarity* [3]. The second characterisation is based on a new labelled transition system (LTS) which modifies the standard one so to reveal what is observable in $L\pi$, that is, what an external observer that behaves like a $L\pi$ process can see by interacting with a $L\pi$ process. Barbed congruence in $L\pi$ coincides with the standard asynchronous ground bisimilarity defined on the new LTS. We then show enhancements of the coinductive proof methods presented by means of *up-to proof techniques*, some of which are standard up-to proof techniques for π -calculus bisimilarities, others are new.

Technical differences of our characterisations with respect to those in π_a and π -calculus [3, 46] are: (i) the labelled bisimilarities of $L\pi$ are congruence relations and therefore do not have to be closed under substitutions to obtain barbed congruence; (ii) the labelled bisimilarities in $L\pi$ are ground, rather than early, which means that they do not need universal quantifications on the received names; (iii) the characterisations in $L\pi$ are proved without the matching construct, which is essential in the proofs in π_a and π -calculus.

Proof techniques for $L\pi$ can be exploited to reason about languages such as Pict, Join, and TyCO, either by directly adapting the techniques to these languages, or by means of encodings into $L\pi$. The theory of $L\pi$ (for instance, its algebraic properties and labelled bisimulations) is also useful in calculi where the usage of some names goes beyond the syntax of $L\pi$. For instance, there could be a distinct set of synchronous names, or names that can be tested for identity (see, for instance, [30]). A type system could be used to distinguish between “ $L\pi$ names” and the other names, and the theory of $L\pi$ can then be applied to the formers.

For simplicity we develop the theory for a *monadic* calculus (where exactly one name may be transmitted); the generalisation to the *polyadic* version (where tuple of names may be transmitted) is straightforward.

1.1 Related work

Calculi similar to Localised π are discussed by Honda and Tokoro [22], Amadio [2], Boreale [7], and Yoshida [62]. A number of characterisations of barbed congruence on asynchronous mobile processes exist [3, 8, 2]. However, in the labelled bisimilarities used, matching transitions of processes have the same labels, therefore laws like (1–5) do not hold.

Other studies on barbed congruence, or similar context-based bisimulations, for mobile processes have been conducted, for instance by Honda and Yoshida [24, 61] Kobayashi, Pierce, and Turner [27], Hennessy and Riely [19] (and, for a coordination language, by Busi, Gorrieri, and Zavattaro [12]). Boreale and Sangiorgi [9] have studied barbed congruence in synchronous π -calculus with capability types and no matching, where $L\pi$ can be treated as a special case. Our characterisations are simpler than those in [9], but the latter are more general, in that they can be applied to several π -calculus languages (although the extension to asynchronous languages is not straightforward). The technical approaches are different: in [9] bisimilarities have a type environment (in fact, closures) whereas our bisimilarities are directly defined on processes.

By the time the writing of this paper has been completed, the theory of $L\pi$ has already been used in some works. In [29], the first author gives an encoding of polyadic $L\pi$ into monadic $L\pi$. Unlike Milner’s encoding of polyadic π into monadic π [31], the encoding in [29] is fully-abstract with respect to barbed congruence. In [54], the second author gives a fully-abstract encoding of *higher-order* $L\pi$ (where processes can be transmitted) into $L\pi$. The theory of $L\pi$ allows proofs simpler than those of analogous results for other π -calculi [46, 49]. Finally, in [30] $L\pi$ is used to give a translational semantics of (an appropriate abstraction of) Cardelli’s distributed object-based programming language *Obliq* [13]. The theory of $L\pi$ (precisely a typed variant of Lemma 5.17) is used to prove the correctness of *object migration*.

In Join and Blue calculus, polymorphic type systems à la ML have been introduced [17, 14]. In both cases, the constraint on the output capability of names is crucial. We believe that similar polymorphic type systems can be defined in $L\pi$.

1.2 Outline

In Section 2 we give syntax and operational semantics of $L\pi$. In Section 3 we recall some common bisimulation-based behavioural equivalences for π -calculi. In Section 4 we present some special processes, the *link processes*, which are important in the theory of $L\pi$. In Section 5 we give the first proof technique for barbed congruence. In Section 6 we give the second proof technique for barbed congruence. In Section 7 we prove that these two proof techniques completely describe barbed congruence. In Section 8 we enhance the second proof technique with a new form of up-to proof technique. Section 9 is entirely devoted to applications: in subsection 9.1 we use link processes to express name substitutions; in Subsection 9.3 we prove that the *delayed input* (a form of non-blocking input prefixing) is derivable in $L\pi$, and present some of its algebraic properties. In Subsection 9.2 we prove a sharpened form of Milner’s *replication theorems* [31]. In Subsection 9.4 we give an optimisation of the encoding of call-by-name λ -calculus and, exploiting delayed input, we derive an encoding of *strong call-by-name*. In Subsection 9.5 we prove some laws for Fournet and Gonthier’s Join-calculus [15]. In Subsection 9.6 we prove some non-full abstraction

and full abstraction results for Boreale's encoding [7] of *external mobility* (communication of free names) in terms of *internal mobility* (communication of private names). Finally, in Subsection 9.7 we prove that Thielecke's axiomatic semantics of the *Continuation Passing Style calculus* [57] is operationally sound.

2 The calculus $L\pi$

$L\pi$ is a subset of asynchronous π -calculus. $L\pi$ has operators of inaction, input prefix, asynchronous output, parallel composition, restriction and replicated input.

Definition 2.1 *Let \mathcal{N} be a countable infinite set of names, ranged over by small letters (a, b, c, \dots, x, y, z). The grammar of $L\pi$ -processes is*

$$P ::= \mathbf{0} \mid a(b).P \mid \bar{a}b \mid P \mid P \mid (\nu a)P \mid !a(b).P$$

with the syntactic constraint that in processes $a(b).P$ and $!a(b).P$ name b may not occur free in P in input position.

Input prefix $a(b).P$ and restriction $(\nu b)P$ acts as *binders* for name b leading to the usual notions of *free* and *bound* occurrences of names, $\text{fn}(\cdot)$ and $\text{bn}(\cdot)$, and α -conversion, Ξ_α . We will identify processes up to α -conversion. More formally we will view process terms as representatives of their equivalence class with respect to Ξ_α , and these representatives will always be chosen so that bound names are distinct from free names. The *names* of a process P , written $\text{n}(P)$, are given by $\text{fn}(P) \cup \text{bn}(P)$. Sometimes, $\text{fn}(P, Q)$ is used as a shorthand for $\text{fn}(P) \cup \text{fn}(Q)$, and similarly for $\text{n}(P, Q)$ and $\text{bn}(P, Q)$. In a statement, a name declared *fresh* is supposed to be different from any other name appearing in the objects of the statement, like processes or substitutions.

Substitutions, ranged over by σ, σ', \dots are functions from \mathcal{N} to \mathcal{N} ; for any process P , we write $P\sigma$ for the process obtained by applying σ to P with renaming possibly involved to avoid capture of free names. The following order precedence when writing processes is assumed: substitution $>$ { restriction, input prefix, replicated input } $>$ parallel composition. We write \bar{a} and $a.P$ when the name transmitted at a is not important. We write $\tau.P$ as an abbreviation for $(\nu a)(\bar{a} \mid a.P)$ where $a \notin \text{fn}(P)$. We write \tilde{a} to denote a tuple of names, such as a_1, \dots, a_n . We write $(\nu \tilde{a})P$ for $(\nu a_1) \dots (\nu a_n)P$.

$L\pi$ does not have a *summation* operator. This is because in asynchronous calculi the meaning of summation, other than input-guarded, is unclear [3]. Nestmann and Pierce have showed that input-guarded summation can be coded up using asynchronous communications [38] (their encoding respects the constraints of $L\pi$).

$L\pi$, like several other dialects of the π -calculus, adopts replicated inputs instead of *recursion*. This is because: (i) replicated input has the same expressive power as full replication [23] and recursion [31, 56]; (ii) replicated input has a simpler semantics and is handy for implementations. The theory and the results presented in this paper would however hold also with full replication or recursion.

The *operational semantics* of $L\pi$ is given by means of *labelled transition system* (LTS) in the SOS style of [45]. The LTS is the standard one, in the *late* style [36, 52], and is presented in Table 1. Transition are of the form $P \xrightarrow{\mu} P'$, where *action* μ can be: τ (interaction), $a(b)$ (input), $\bar{a}b$ (free output) and $\bar{a}(b)$ (bound output, that is the emission of a private name b at a). In these actions, a is the *subject* and b the *object*. Free and bound names of actions and processes are defined as usual. We write $\xrightarrow{\hat{\mu}}$ to mean $P \xrightarrow{\mu} Q$, if $\mu \neq \tau$, and either $P = Q$ or $P \xrightarrow{\tau} Q$, if $\mu = \tau$. Relation \Longrightarrow is the reflexive and transitive closure of $\xrightarrow{\tau}$; moreover, $\xrightarrow{\hat{\mu}}$ stands for $\Longrightarrow \xrightarrow{\mu} \Longrightarrow$, and $\xrightarrow{\hat{\mu}}$ for $\xrightarrow{\mu}$ if $\mu \neq \tau$, and for \Longrightarrow if $\mu = \tau$.

Finally, in the sequel, we use the symbol \equiv to denote *structural congruence*, a relation used to rearrange the structure of processes [31].

Definition 2.2 (Structural congruence) Structural congruence, \equiv , is the smallest congruence relation satisfying the axioms below:

$\text{inp: } \frac{}{a(x).P \xrightarrow{a(x)} P}$	$\text{out: } \frac{}{\bar{a}b.P \xrightarrow{\bar{a}b} P}$
$\text{open: } \frac{P \xrightarrow{\bar{a}b} P' \quad a \neq b}{(\nu b)P \xrightarrow{\bar{a}(b)} P'}$	$\text{close: } \frac{P \xrightarrow{\bar{a}(c)} P' \quad Q \xrightarrow{a(c)} Q'}{P \mid Q \xrightarrow{\tau} (\nu c)(P' \mid Q')}$
$\text{com: } \frac{P \xrightarrow{\bar{a}b} P' \quad Q \xrightarrow{a(x)} Q'}{P \mid Q \xrightarrow{\tau} P' \mid Q'\{b/x\}}$	$\text{par: } \frac{P \xrightarrow{\mu} P' \quad \text{bn}(\mu) \cap \text{fn}(Q) = \emptyset}{P \mid Q \xrightarrow{\mu} P' \mid Q}$
$\text{new: } \frac{P \xrightarrow{\mu} P' \quad a \notin \text{n}(\mu)}{(\nu a)P \xrightarrow{\mu} (\nu a)P'}$	$\text{rep: } \frac{}{!a(x).P \xrightarrow{a(x)} P \mid !a(x).P}$

Table 1: Labelled transition system for $L\pi$

-
- $P \mid \mathbf{0} \equiv P$, $P \mid Q \equiv Q \mid P$, $P \mid (Q \mid R) \equiv (P \mid Q) \mid R$
 - $(\nu a)\mathbf{0} \equiv \mathbf{0}$, $(\nu a)(\nu b)P \equiv (\nu b)(\nu a)P$, $(\nu a)(P \mid Q) \equiv P \mid (\nu a)Q$ if $a \notin \text{fn}(P)$.

3 Some background on behavioural equivalences

A crucial notion in a process calculus is that of *behavioural equality* between processes. As said in the introduction, we focus on bisimulation-based behavioural equivalences, and more precisely on *barbed congruence*. Barbed congruence can be defined in any calculus possessing: (i) an *interaction relation* (the τ -steps in the π -calculus), modelling the evolution of the system; and (ii) an *observability predicate* \Downarrow_a for each name a , which detects the possibility of a process of accepting a communication with the environment at a . More precisely, we write $P \Downarrow_a$ if P can make an output action whose subject is a , that is, if there exist P' and b such that $P \xrightarrow{\bar{a}b} P'$ or $P \xrightarrow{\bar{a}(d)} P'$. We write $P \Downarrow_a$ if $P \Longrightarrow P'$ and $P' \Downarrow_a$. Unlike synchronous π -calculus, in asynchronous calculi it is natural to restrict the observation to output actions [3]. The reason is that in asynchronous calculi the observer has no direct way of knowing when a message emitted is received. Below, we define barbed congruence on a generic subset \mathcal{P} of π -calculus processes. A \mathcal{P} -context is a process of \mathcal{P} with a single hole $[\cdot]$ in it.

Definition 3.1 (Barbed relations) *A symmetric relation \mathcal{S} on processes is a barbed bisimulation if $P \mathcal{S} Q$ implies:*

1. If $P \xrightarrow{\tau} P'$ then there exists Q' such that $Q \Longrightarrow Q'$ and $P' \mathcal{S} Q'$.
2. If $P \Downarrow_a$ then $Q \Downarrow_a$.

Two processes P and Q are barbed bisimilar, written $P \dot{\sim} Q$, if $P \mathcal{S} Q$ for some barbed bisimulation \mathcal{S} . Let \mathcal{P} be a set of π -calculus processes, and $P, Q \in \mathcal{P}$. We say that P and Q are barbed congruent in \mathcal{P} , written $P \cong_{\mathcal{P}} Q$, if for each \mathcal{P} -context $C[\cdot]$, it holds that $C[P] \dot{\sim} C[Q]$.

Characterisations of barbed congruence in terms of labelled bisimilarities are usually given on the class of *image-finite processes*, by exploiting the n -approximants of the labelled equivalence.

Definition 3.2 *The class of image-finite processes is the largest subset \mathcal{I} of π -processes which is derivation closed and such that $P \in \mathcal{I}$ implies that, for all μ , the set $\{P' : P \xrightarrow{\mu} P'\}$, quotiented by alpha conversion, is finite.*

In π -calculi, barbed congruence coincides with the closure under substitutions of early bisimilarity [46, 3]. In asynchronous calculi *without* matching, like $L\pi$, early bisimilarity is a congruence and it coincides with its simpler *ground* variant [20, 48], which differ from the early one in that there is no universal quantification in the input clause.

Definition 3.3 *A symmetric relation \mathcal{S} on π -terms is an σ -bisimulation if $P \mathcal{S} Q$, $P \xrightarrow{\mu} P'$, μ is not an input and $\text{bn}(\mu) \cap \text{fn}(Q) = \emptyset$, implies that there exists Q' such that $Q \xrightarrow{\hat{\mu}} Q'$ and $P' \mathcal{S} Q'$.*

Definition 3.4 (Ground bisimilarities)

- Synchronous ground bisimulation is the largest σ -bisimulation \mathcal{S} on processes such that $P \mathcal{S} Q$ and $P \xrightarrow{a(b)} P'$, with $b \notin \text{fn}(Q)$, implies that there exists Q' such that $Q \xrightarrow{a(b)} Q'$ and $P' \mathcal{S} Q'$.

Two processes P and Q are synchronous ground bisimilar, written $P \approx Q$, if $P \mathcal{S} Q$ for some synchronous ground bisimulation \mathcal{S} .

- Asynchronous ground bisimulation is the largest σ -bisimulation \mathcal{S} on processes such that $P \mathcal{S} Q$ and $P \xrightarrow{a(b)} P'$, with $b \notin \text{fn}(Q)$, implies that there exists Q' such that:

1. either $Q \xrightarrow{a(b)} Q'$ and $P' \mathcal{S} Q'$
2. or $Q \Longrightarrow Q'$ and $P' \mathcal{S} (Q' \mid \bar{a}b)$.

Two processes P and Q are asynchronous ground bisimilar, written $P \approx_a Q$, if $P \mathcal{S} Q$ for some asynchronous ground bisimulation \mathcal{S} .

Sometimes, it may be useful to count the number of silent moves performed by a process. The *synchronous expansion* [5], written \lesssim , is an asymmetric variant of \approx such that $P \lesssim Q$ holds if $P \approx Q$, and Q has at least as many τ -moves as P .

Similarly, one can define *asynchronous expansion*.

Definition 3.5 (Expansions)

- A relation \mathcal{S} on processes is a synchronous ground expansion if $P \mathcal{S} Q$ implies:

1. If $P \xrightarrow{\mu} P'$, $\mu \in \{\tau, \bar{a}b, \bar{a}(b), a(b)\}$ and $\text{bn}(\mu) \cap \text{fn}(Q) = \emptyset$, then there exists Q' such that $Q \xrightarrow{\hat{\mu}} Q'$ and $P' \mathcal{S} Q'$.
2. If $Q \xrightarrow{\mu} Q'$, $\mu \in \{\tau, \bar{a}b, \bar{a}(b), a(b)\}$ and $\text{bn}(\mu) \cap \text{fn}(P) = \emptyset$, then there exists P' such that $P \xrightarrow{\hat{\mu}} P'$ and $P' \mathcal{S} Q'$.

We write $P \lesssim Q$ if $P \mathcal{S} Q$ for some synchronous ground expansion \mathcal{S} .

- A relation \mathcal{S} on processes is an asynchronous ground expansion if $P \mathcal{S} Q$ implies:

1. If $P \xrightarrow{\mu} P'$, μ is not an input, and $\text{bn}(\mu) \cap \text{fn}(Q) = \emptyset$, then there exists Q' such that $Q \xrightarrow{\hat{\mu}} Q'$ and $P' \mathcal{S} Q'$.
2. If $P \xrightarrow{a(b)} P'$, $b \notin \text{fn}(Q)$, there exists Q' such that:
 - (a) either $Q \xrightarrow{a(b)} Q'$ and $P' \mathcal{S} Q'$
 - (b) or $Q \xrightarrow{\tau} Q'$ and $P' \mathcal{S} (Q' \mid \bar{a}b)$.
3. If $Q \xrightarrow{\mu} Q'$, μ is not an input, and $\text{bn}(\mu) \cap \text{fn}(P) = \emptyset$, then there exists P' such that $P \xrightarrow{\hat{\mu}} P'$ and $P' \mathcal{S} Q'$;
4. if $Q \xrightarrow{a(b)} Q'$, $b \notin \text{fn}(P)$, then there exists P' such that:

- (a) either $P \xrightarrow{a(b)} P'$ and $P' S Q'$
(b) or $P \xrightarrow{\hat{t}} P'$ and $(P \mid \bar{a}b) S Q'$.

We write $P \lesssim_a Q$, if $P S Q$ for some asynchronous ground expansion S .

4 The link processes

The theory of $L\pi$ is based on special processes called *links* which behave as name buffers receiving names at one end-point and retransmitting them at the other end-point (in the π -calculus literature, links are sometimes called forwarders [24] or wires [56]).

Definition 4.1 (Static link) *Given any two names a and b , we call static link the process below:*

$$a \triangleright b \stackrel{\text{def}}{=} !a(x). \bar{b}x.$$

We sometimes use a more sophisticated form of link $a \rightarrow b$, which does not perform free outputs: the name sent at b is not x , but a link to x (this is the definition of links in calculi where all outputs emit private names [50]).

Definition 4.2 (Dynamic link) *Given two names a and b , we call dynamic link the process defined by the following recursive definition:*

$$a \rightarrow b \stackrel{\text{def}}{=} !a(x). (\nu c)(\bar{b}c \mid c \rightarrow x).$$

Being recursively defined, the process $a \rightarrow b$ is not in $L\pi$. However, there exists a process in $L\pi$ which is synchronous bisimilar to it. In the following we explain how this process can be built up. In [31], Milner shows that recursive definitions can be encoded, up to bisimilarity, in terms of replication. When applying Milner's encoding to a dynamic link we get a processes which does not respect the $L\pi$ constraint on the output capability. This problem can be avoided by rewriting the definition of dynamic links thus:

$$a \rightarrow b \stackrel{\text{def}}{=} !a(x). \text{out}(b, x)$$

where $\text{out}(b, x)$ is recursively defined as:

$$\text{out}(b, x) \stackrel{\text{def}}{=} (\nu c)(\bar{b}c \mid !c(y). \text{out}(x, y)).$$

Process $\text{out}(b, x)$ can be expressed in (polyadic) $L\pi$ in terms of replication as follows:

$$\text{out}(b, x) \approx (\nu o)(\bar{o}(b, x) \mid !o(b, x). (\nu c)(\bar{b}c \mid !c(y). \bar{o}(x, y))).$$

As already pointed out in Section 3, in asynchronous calculi, the relation \approx is a congruence. So, the process $a \rightarrow b$ can be rewritten, up to \approx , in (polyadic) $L\pi$. Finally, by exploiting the encoding $\{\cdot\}$ defined below, we get the desired process of $L\pi$ which is bisimilar to the recursive process $a \rightarrow b$. The encoding $\{\cdot\}$ is a slight variant of Milner's encoding [31] of polyadic processes into monadic ones². $\{\cdot\}$ is an homomorphism on all operators except input and output for which we have:

- $\{a(x_1, x_2). P\} \stackrel{\text{def}}{=} a(w). (\nu c_1 c_3)(\bar{w}c_1 \mid c_1(c_2). (\bar{c}_2 c_3 \mid c_3(x_1). c_1(x_2). \{P\}))$
- $\{\bar{a}(b_1, b_2)\} \stackrel{\text{def}}{=} (\nu w)(\bar{a}w \mid w(c_1). (\nu c_2)(\bar{c}_1 c_2 \mid c_2(c_3). (\bar{c}_3 b_1 \mid \bar{c}_1 b_2)))$.

To conclude the section we show how links can be joined with each other.

²For our purposes it suffices to consider the encoding where only pairs are taken into account.

$$\begin{array}{lll}
\llbracket P_1 \mid P_2 \rrbracket \stackrel{\text{def}}{=} \llbracket P_1 \rrbracket \mid \llbracket P_2 \rrbracket & \llbracket a(x). P \rrbracket \stackrel{\text{def}}{=} a(x). \llbracket P \rrbracket & \llbracket !a(x). P \rrbracket \stackrel{\text{def}}{=} !a(x). \llbracket P \rrbracket \\
\llbracket (\nu a)P \rrbracket \stackrel{\text{def}}{=} (\nu a)\llbracket P \rrbracket & \llbracket \bar{a}b \rrbracket \stackrel{\text{def}}{=} (\nu c)(\bar{a}c \mid c \rightarrow b) & \llbracket \mathbf{0} \rrbracket \stackrel{\text{def}}{=} \mathbf{0}
\end{array}$$

Table 2: The encoding of free outputs in terms of bound outputs

Proposition 4.3 *Let a and b be names different from c . Then:*

1. $(\nu b)(a \triangleright b \mid b \triangleright c) \gtrsim a \triangleright c$
2. $(\nu b)(a \rightarrow b \mid b \rightarrow c) \gtrsim a \rightarrow c$
3. $(\nu b)(a \triangleright b \mid b \rightarrow c) \gtrsim a \rightarrow c$
4. $(\nu b)(a \rightarrow b \mid b \triangleright c) \gtrsim a \rightarrow c$.

Proof: Parts 1, 3, 4 are proved by simply exhibiting the appropriate expansion relations. Part 2 has been already proved in [7] and requires up-to context proof techniques. \square

5 A “translation-based” proof technique

In this section, we give a proof technique for barbed congruence in $L\pi$ based on an encoding of free outputs in terms of bound outputs (see Table 2). The encoding, written $\llbracket \cdot \rrbracket$, is an homomorphism on all operators except output. The output particle $\bar{a}b$ is mapped into the process $(\nu c)(\bar{a}c \mid c \rightarrow b)$ where $c \notin \{a, b\}$. Our encoding is essentially the asynchronous version of an encoding used by Boreale [7] to compare internal and external mobility. In Boreale’s encoding, an output $\bar{a}b$ is mapped onto the synchronous process $(\nu c)(\bar{a}c.c \rightarrow b)$. This process is behaviourally the same as $(\nu c)(\bar{a}c \mid c \rightarrow b)$: in both cases the link $c \rightarrow b$ becomes active only when the bound output at a is consumed. Note that the process $(\nu c)(\bar{a}c \mid c \rightarrow b)$ coincides with the recursive definition $\text{out}(a, b)$ seen in Section 4.

In Section 5.1, we present some results on $\llbracket \cdot \rrbracket$ already proved by Boreale [7] for its encoding and that trivially apply to our encoding as well. Then, in Section 5.2, we give the proof technique.

5.1 Background

The encoding $\llbracket \cdot \rrbracket$ commutes with substitutions, i.e., for each substitution σ it holds that $\llbracket P\sigma \rrbracket = \llbracket P \rrbracket\sigma$. In [7] Boreale proves an operational correspondence between processes P and $\llbracket P \rrbracket$; he also gives an adequacy result for $\llbracket \cdot \rrbracket$ with respect to barbed bisimulation.

Lemma 5.1 (Boreale [7]) *Let P be a process in $L\pi$.*

1. *Suppose that $P \xrightarrow{\mu} P'$. Then we have:*

- (a) *if $\mu = a(c)$ then $\llbracket P \rrbracket \xrightarrow{a(c)} \gtrsim \llbracket P' \rrbracket$*
- (b) *if $\mu = \bar{a}b$ then $\llbracket P \rrbracket \xrightarrow{\bar{a}(c)} \gtrsim c \rightarrow b \mid \llbracket P' \rrbracket$, with $c \notin \text{fn}(P')$*
- (c) *if $\mu = \bar{a}(b)$ then $\llbracket P \rrbracket \xrightarrow{\bar{a}(c)} \gtrsim (\nu b)(c \rightarrow b \mid \llbracket P' \rrbracket)$, with $c \notin \text{fn}(P')$*
- (d) *if $\mu = \tau$ then $\llbracket P \rrbracket \xrightarrow{\tau} \gtrsim \llbracket P' \rrbracket$.*

2. *Suppose that $\llbracket P \rrbracket \xrightarrow{\mu} P_1$. Then there exists $P' \in L\pi$ such that:*

- (a) if $\mu = a(c)$ then $P \xrightarrow{a(c)} P'$, with $P_1 \succeq \llbracket P' \rrbracket$
 (b) if $\mu = \bar{a}(c)$ then:
 i. either $P \xrightarrow{\bar{a}b} P'$, with $c \notin \text{fn}(P')$ and $P_1 \succeq (c \rightarrow b \mid \llbracket P' \rrbracket)$
 ii. or $P \xrightarrow{\bar{a}(b)} P'$, with $c \notin \text{fn}(P')$ and $P_1 \succeq (\nu b)(c \rightarrow b \mid \llbracket P' \rrbracket)$
 (c) if $\mu = \tau$ then $P \xrightarrow{\tau} P'$ with $P_1 \succeq \llbracket P' \rrbracket$.

The proof of the lemma above relies on Proposition 4.3(2) and a technical but important lemma that we report below.

Lemma 5.2 (Boreale [7]) *Let P be an $L\pi$ -process, and a and b two names such that $a \neq b$ and a does not occur free in P in input-subject position. Then:*

$$(\nu a)(a \rightarrow b \mid \llbracket P \rrbracket) \succeq \llbracket P \rrbracket \{b/a\}.$$

From Lemma 5.1 Boreale derives the following adequacy result for $\llbracket \cdot \rrbracket$.

Theorem 5.3 (Boreale [7]) *Let P and Q be two processes in $L\pi$. Then:*

$$P \approx Q \text{ iff } \llbracket P \rrbracket \approx \llbracket Q \rrbracket.$$

5.2 The proof technique

For technical reasons, it is convenient to define a calculus, called $\mathcal{L}\pi$, whose operators are the same as those of $L\pi$ but with the output construct $\bar{a}b$ replaced by its translation $\llbracket \bar{a}b \rrbracket$. Formally, the syntax of $\mathcal{L}\pi$ is the following:

$$P ::= \mathbf{0} \mid a(x).P \mid \llbracket \bar{a}b \rrbracket \mid P \mid P \mid (\nu a)P \mid !a(x).P$$

with the same constraint on received names as in $L\pi$. $\mathcal{L}\pi$ is the image of $L\pi$ under the encoding $\llbracket \cdot \rrbracket$.

Lemma 5.4 *If P is an $L\pi$ -process then $\llbracket P \rrbracket$ is an $\mathcal{L}\pi$ -process. Vice versa, for each $\mathcal{L}\pi$ -process Q there exists an $L\pi$ -process P such that $\llbracket P \rrbracket = Q$.*

It is easy to see that $\mathcal{L}\pi$ is closed under under labelled transitions:

Lemma 5.5 *Let P be an $\mathcal{L}\pi$ -process. If $P \xrightarrow{\mu} P_1$ then $P_1 \in \mathcal{L}\pi$.*

Proof: By structural induction. The most interesting case is when

$$P = \llbracket \bar{a}b \rrbracket \stackrel{\text{def}}{=} (\nu c)(\bar{a}c \mid c \rightarrow b) = (\nu c)(\bar{a}c \mid !c(x). \llbracket \bar{b}x \rrbracket).$$

In this case, $\mu = \bar{a}(c)$ and $P_1 = !c(x). \llbracket \bar{b}x \rrbracket$ which, by definition, is in $\mathcal{L}\pi$. \square

The proof technique to verify if two $L\pi$ -processes are barbed congruent consists in translating them, by means of $\llbracket \cdot \rrbracket$, and then checking if their images are related by the bisimilarity \approx_a defined below. The relation \approx_a is a slight variant of the asynchronous ground bisimilarity (c.f. Definition 3.4) in which the output particle $\bar{a}b$ in clause 2 is replaced by $\llbracket \bar{a}b \rrbracket$.

Definition 5.6 (\approx_a -bisimilarity) *A symmetric relation S on processes of $\mathcal{L}\pi$ is a \approx_a -bisimulation if whenever $P S Q$ the following holds:*

1. If $P \xrightarrow{\tau} P'$, then there exists Q' such that $Q \Longrightarrow Q'$ and $P' S Q'$.
2. If $P \xrightarrow{\bar{a}(b)} P'$, $b \notin \text{fn}(Q)$, then there exists Q' such that $Q \xrightarrow{\bar{a}(b)} Q'$ and $P' S Q'$.
3. If $P \xrightarrow{a(b)} P'$, $b \notin \text{fn}(Q)$, then there exists Q' such that:

- (a) either $Q \xrightarrow{a(b)} Q'$ and $P' \mathcal{S} Q'$
- (b) or $Q \Longrightarrow Q'$ and $P' \mathcal{S} (Q' \mid \llbracket \bar{a}b \rrbracket)$.

Processes P and Q are \approx_a -bisimilar, written $P \approx_a Q$, if $P \mathcal{S} Q$ for some \approx_a -bisimulation \mathcal{S} .

Relation \approx_a is designed to be used on $\mathcal{L}\pi$ -processes and therefore its definition does not contain clauses for free output actions. In order to prove that \approx_a is a congruence relation over $\mathcal{L}\pi$ we adapt the up-to expansion proof technique of [55].

Definition 5.7 (\approx_a -bisimulation up to \gtrsim and \approx) *A symmetric relation \mathcal{S} is a \approx_a -bisimulation up to \gtrsim and \approx if whenever $P \mathcal{S} Q$ the following holds:*

1. If $P \xrightarrow{\tau} P'$, then there exists Q' such that $Q \Longrightarrow Q'$ and $P' \gtrsim \mathcal{S} \approx Q'$.
2. If $P \xrightarrow{\bar{a}(b)} P'$, $b \notin \text{fn}(Q)$, then there exists Q' such that $Q \xrightarrow{\bar{a}(b)} Q'$ and $P' \gtrsim \mathcal{S} \approx Q'$.
3. If $P \xrightarrow{ab} P'$, $b \notin \text{fn}(P, Q)$, then there exists Q' such that:

- (a) either $Q \xrightarrow{ab} Q'$ and $P' \gtrsim \mathcal{S} \approx Q'$
- (b) or $Q \Longrightarrow Q'$ and $P' \gtrsim \mathcal{S} \approx (Q' \mid \llbracket \bar{a}b \rrbracket)$.

Lemma 5.8 *If \mathcal{S} is a \approx_a -bisimulation up to \gtrsim and \approx then $\mathcal{S} \subseteq \approx_a$.*

Proof: The proof is analogous to that in [55]. If \mathcal{S} is a \approx_a -bisimulation up to \gtrsim and \approx , then one shows that the relation $\approx \mathcal{S} \approx$ is a \approx_a -bisimulation. This follows from the transitivity of \approx and the fact that \approx is preserved by parallel composition (The latter result is necessary to deal with clause (3b) of Definition 5.6). Finally, since $\mathcal{S} \subseteq \approx \mathcal{S} \approx \subseteq \approx_a$, we can conclude. \square

In the sequel, we often use a \approx_a -bisimulation up to \equiv proof technique. The soundness of this technique follows from Lemma 5.8 and the fact that \equiv is contained in \gtrsim (and therefore also in \approx).

The following lemma gives us some information about the structure of the $\mathcal{L}\pi$ -processes which may perform an output action. Part 2 of Lemma 5.9 will be needed to prove that \approx_a is preserved by parallel composition.

Lemma 5.9 *Let P be an $\mathcal{L}\pi$ -process.*

1. If $P \xrightarrow{\bar{a}(c)} P_1$ then $P \equiv (\nu \tilde{z})((\nu c)(\bar{a}c \mid c \rightarrow b) \mid P_2)$ and $P_1 \equiv (\nu \tilde{z})(c \rightarrow b \mid P_2)$ for some \tilde{z} , b and P_2 such that $\{a, c\} \cap \tilde{z} = \emptyset$ and $c \notin \text{fn}(P_2)$.
2. If $P \xrightarrow{\bar{a}(c)} P_1$ then $P \approx (\nu c)(\llbracket \bar{a}c \rrbracket \mid P_1)$.

Proof:

1. By transition induction.
2. By part 1 $P \equiv (\nu \tilde{z})((\nu c)(\bar{a}c \mid c \rightarrow b) \mid P_2)$ and $P_1 \equiv (\nu \tilde{z})(c \rightarrow b \mid P_2)$ for some \tilde{z} , b and P_2 such that $\{a, c\} \cap \tilde{z} = \emptyset$ and $c \notin \text{fn}(P_2)$. Picking some fresh name d we have, using proposition 4.3(2):

$$\begin{aligned}
P &\equiv (\nu \tilde{z})((\nu d)(\bar{a}d \mid d \rightarrow b) \mid P_2) \\
&\approx (\nu \tilde{z})((\nu d)(\bar{a}d \mid (\nu c)(d \rightarrow c \mid c \rightarrow b)) \mid P_2) \\
&\equiv (\nu c)((\nu d)(\bar{a}d \mid d \rightarrow c) \mid (\nu \tilde{z})(c \rightarrow b \mid P_2)) \\
&\equiv (\nu c)(\llbracket \bar{a}c \rrbracket \mid P_1).
\end{aligned}$$

\square

Lemma 5.10 *Let P and Q be two $\mathcal{L}\pi$ -processes such that $P \approx_a Q$. Then:*

1. $(\nu a)P \approx_a (\nu a)Q$
2. $P \mid R \approx_a Q \mid R$, for all $\mathcal{L}\pi$ -process R .

Proof: Here we give a sketch of the proof. A detailed proof can be found in Appendix A.1

1. We show that the relation

$$S = \{((\nu a)P, (\nu a)Q) : P, Q \in \mathcal{L}\pi \text{ and } P \approx_a Q\}$$

is a \approx_a -bisimulation up-to structural congruence. The proof is straightforward because the output actions performed by an $\mathcal{L}\pi$ -process are always bound and therefore the restriction operator cannot bind names in output object position. We work up to structural congruence when dealing with the asynchronous clause for input.

2. We prove that the relation

$$S = \{((\nu \tilde{a})(P \mid R), (\nu \tilde{a})(Q \mid R)) : P, Q, R \in \mathcal{L}\pi \text{ and } P \approx_a Q\}$$

is a \approx_a -bisimulation up to \gtrsim and \approx . The proof requires both the up-to proof technique of Definition 5.7 and Lemma 5.9. In general, proving that a ground bisimulation is preserved by parallel composition is hard. In our case the proof is simple because processes in $\mathcal{L}\pi$ never perform free output actions.

□

We can now prove that \approx_a is an equivalence relation.

Lemma 5.11 *Let P , Q and R be $\mathcal{L}\pi$ -processes. Then:*

1. $P \approx_a P$
2. $P \approx_a Q$ implies $Q \approx_a P$
3. $P \approx_a Q$ and $Q \approx_a R$ implies $P \approx_a R$.

Proof: The only nontrivial property is transitivity. We essentially need to prove two results:

- \approx_a is preserved by injective substitutions. The proof is analogous to that of \approx in the π -calculus.
- $P \approx_a Q$ and $b \notin \text{fn}(P, Q)$ implies $P \mid \llbracket \bar{a}b \rrbracket \approx_a Q \mid \llbracket \bar{a}b \rrbracket$. This result is necessary to deal with clause (3b) of Definition 5.6 and is just a particular case of Lemma 5.10(2). Notice that the proof of Lemma 5.10(2) does not rely on the transitivity of \approx_a .

□

Lemma 5.12 *Let P and Q be two $\mathcal{L}\pi$ -processes such that $P \approx_a Q$. Then:*

1. $a(x).P \approx_a a(x).Q$
2. $!a(x).P \approx_a !a(x).Q$.

Proof: Here we give a sketch of the proof. A detailed proof can be found in Appendix A.1

1. We prove that the relation

$$S = \{(a(x).P, a(x).Q) : P, Q \in \mathcal{L}\pi \text{ and } P \approx_a Q\}$$

is a \approx_a -bisimulation. Since \approx_a is in ground style it suffices to prove that \approx_a is preserved by injective substitution. The proof is analogous to that of \approx in the π -calculus.

2. We prove that the relation \mathcal{S} defined below

$$\{(P_1 \mid !a(x).Q_1, P_2 \mid !a(x).Q_2) : P_1, P_2, Q_1, Q_2 \in \mathcal{L}\pi, P_1 \succ_a P_2, Q_1 \succ_a Q_2\}$$

is a \succ_a -bisimulation up to structural congruence (it is a special case of the proof technique of Definition 5.7). The proof relies on the fact that \succ_a is preserved by injective substitutions, parallel composition, and restriction. By transitivity of \succ_a (Lemma 5.11(3)) we then conclude.

□

By Lemmas 5.10, 5.11, and 5.12 we can conclude that \succ_a is a congruence.

Corollary 5.13 \succ_a is a congruence relation.

Finally, we can prove the soundness of our “translation-based” technique for barbed congruence in $\mathcal{L}\pi$.

Theorem 5.14 (Soundness) Let P and Q be two processes in $\mathcal{L}\pi$. Then:

$$\llbracket P \rrbracket \succ_a \llbracket Q \rrbracket \text{ implies } P \cong_{\mathcal{L}\pi} Q.$$

Proof: By Lemmas 5.4 and Corollary 5.13 it holds that $\llbracket C[P] \rrbracket \succ_a \llbracket C[Q] \rrbracket$ for any context $C[\cdot]$ in $\mathcal{L}\pi$. Since $\succ_a \subset \dot{\approx}$, it holds that $\llbracket C[P] \rrbracket \dot{\approx} \llbracket C[Q] \rrbracket$ and therefore, by Theorem 5.3, $C[P] \dot{\approx} C[Q]$. □

Corollary 5.15 Let P and Q be two processes in $\mathcal{L}\pi$. Then:

$$\llbracket P \rrbracket \approx \llbracket Q \rrbracket \text{ implies } P \cong_{\mathcal{L}\pi} Q.$$

Proof: \approx implies \succ_a . By applying Theorem 5.14 we get the result. □

Remark 5.16 Theorem 5.14 (resp. Corollary 5.15) does not hold when replacing \succ_a (resp. \approx) and barbed congruence with their expansion variants, respectively. This is because, as we will see in the next section, the encoding $\llbracket \cdot \rrbracket$ may introduce a few τ -steps changing the balance of silent moves between two processes. Had such an expansion variant of Theorem 5.14 (and Corollary 5.15) been available, then proof of a key result in Section 9.3 would have been much simpler (see Remark 9.11).

The encoding $\llbracket \cdot \rrbracket$ is essentially based on the law below, relating free and bound output actions:

$$\overline{ab} \cong_{\mathcal{L}\pi} (\nu c)(\overline{ac} \mid c \rightarrow b) \tag{6}$$

However, in $\mathcal{L}\pi$, it holds an even simpler law which relates free and bound output actions. We recall that $c \triangleright b$ denotes the static link of Definition 4.1.

Lemma 5.17 Let a and b be two names different from c . Then:

$$\overline{ab} \cong_{\mathcal{L}\pi} (\nu c)(\overline{ac} \mid c \triangleright b).$$

Proof: We code up, via $\llbracket \cdot \rrbracket$, both members of the equation obtaining, respectively:

$$(\nu d)(\overline{ad} \mid d \rightarrow b) \text{ and } (\nu c)((\nu d)(\overline{ad} \mid d \rightarrow c) \mid c \rightarrow b).$$

By Proposition 4.3(2) the two processes above are synchronous bisimilar. By Corollary 5.15, we can conclude. □

From Lemma 5.17 we can derive a “translation based” proof technique for barbed congruence simpler than that given by Theorem 5.14, whereby in the encoding $\llbracket \cdot \rrbracket$, static links $c \triangleright b$ are used instead of dynamic links $c \rightarrow b$. However, as we will prove in Section 7, this proof technique is sound but not complete, that is, it does not completely describe barbed congruence.

$$\begin{array}{c}
\text{free-out: } \frac{P \xrightarrow{\bar{a}b} P' \quad p \notin \text{fn}(P)}{P \xrightarrow{\bar{a}(p)} (p \triangleright b \mid P')} \\
\text{sync: } \frac{P \xrightarrow{\tau} P'}{P \xrightarrow{\tau} P'} \\
\text{bound-out: } \frac{P \xrightarrow{\bar{a}(b)} P' \quad p \notin \text{fn}(P)}{P \xrightarrow{\bar{a}(p)} (\nu b)(p \triangleright b \mid P')} \\
\text{input: } \frac{P \xrightarrow{a(b)} P'}{P \xrightarrow{a(b)} P'}
\end{array}$$

Table 3: A new labelled transition system for $L\pi$

6 A “run-time” proof technique

The main drawback of the proof technique of Theorem 5.14 is that the encoding $\llbracket \cdot \rrbracket$ adds a dynamic link to all outputs in the source processes, slowing down computation. A process $\llbracket P \rrbracket$ will normally take more steps to simulate the computation of P . For instance, if P is

$$\bar{a}b \mid a(x). \bar{x}c \mid b(z). \bar{z}w$$

then P needs two τ -steps before producing an output at c , whereas its image

$$\llbracket \bar{a}b \rrbracket \mid a(x). \llbracket \bar{x}c \rrbracket \mid b(z). \llbracket \bar{z}w \rrbracket$$

will take 5 steps. We conjecture that in $L\pi$ the encoding $\llbracket \cdot \rrbracket$ does not introduce divergences, that is, infinite internal computations. Notice that if we would add full replication in $L\pi$ the encoding would not be divergence-free. As an example, take the process

$$P \stackrel{\text{def}}{=} \bar{a}b \mid a(x). !\bar{x}c$$

This process does not diverge, but $\llbracket P \rrbracket$ does.

In this section, we introduce a more powerful technique based on a new LTS $\xrightarrow{\mu}$ for $L\pi$. The new LTS, reported in Table 3, is defined on top of the original one, and transforms the output of a name b into the output of a fresh *pointer* p to b . We call p a pointer to b because a link $p \triangleright b$ is introduced through which any output along p is redirected onto b . The new LTS makes explicit the constraint that in $L\pi$ only the output capability of names may be transmitted, by transforming the occurrence of a name in output object position with an occurrence of the same name in output subject position.

The weak transitions $\xRightarrow{\mu}$ and $\xRightarrow{\tau}$ for the new LTS are defined from the strong transitions $\xrightarrow{\mu}$ and $\xrightarrow{\tau}$ in the usual way. We write $\xrightarrow{\tau} \approx_a$ to denote the relation obtained by replacing in the definition of asynchronous ground bisimulation (Definition 3.4) arrow \longrightarrow with $\xrightarrow{\tau}$ and arrow \Longrightarrow with $\xRightarrow{\tau}$. We prove that asynchronous ground bisimulation defined on the new LTS implies barbed congruence. To avoid reasoning with two LTSs, we reformulate the definition of $\xrightarrow{\tau} \approx_a$ on the original LTS.

Definition 6.1 (Link bisimilarity) *A symmetric relation \mathcal{S} on $L\pi$ -processes is a link bisimulation if whenever $P \mathcal{S} Q$ the following holds:*

1. If $P \xrightarrow{\tau} P'$ then $Q \xRightarrow{\tau} Q'$ and $P' \mathcal{S} Q'$.
2. If $P \xrightarrow{a(p)} P'$, and $p \notin \text{fn}(Q)$, then
 - (a) either $Q \xrightarrow{a(p)} Q'$ and $P' \mathcal{S} Q'$
 - (b) or $Q \xRightarrow{\tau} Q'$ and $P' \mathcal{S} (Q' \mid \bar{a}p)$.
3. If $P \xrightarrow{\bar{a}b} P'$, then

- (a) either $Q \xrightarrow{\bar{a}d} Q'$ and $\exists p \notin \text{fn}(P, Q)$ such that $(p \triangleright b \mid P') \mathcal{S} (p \triangleright d \mid Q')$
- (b) or $Q \xrightarrow{\bar{a}(c)} Q'$, with $c \notin \text{fn}(P)$, and $\exists p \notin \text{fn}(P, Q)$ such that $(p \triangleright b \mid P') \mathcal{S} (\nu c)(p \triangleright c \mid Q')$.

4. If $P \xrightarrow{\bar{a}(c)} P'$, with $c \notin \text{fn}(Q)$, then

- (a) either $Q \xrightarrow{\bar{a}b} Q'$ and $\exists p \notin \text{fn}(P, Q)$ such that $(\nu c)(p \triangleright c \mid P') \mathcal{S} (p \triangleright b \mid Q')$
- (b) or $Q \xrightarrow{\bar{a}(c)} Q'$, $\exists p \notin \text{fn}(P, Q)$ such that $(\nu c)(p \triangleright c \mid P') \mathcal{S} (\nu c)(p \triangleright c \mid Q')$.

P and Q are link bisimilar, written $P \approx_1 Q$, if $P \mathcal{S} Q$ for some link bisimulation \mathcal{S} .

The only difference between link bisimilarity and asynchronous ground bisimilarity is in the clauses for output actions: In link bisimilarity the name emitted by the two processes may be different. To mask this difference, links are added in the derivatives. It is immediate to see that $\xrightarrow{\bar{a}}_a$ and \approx_1 coincide.

Lemma 6.2 *Let P and Q be two processes in $L\pi$. Then:*

$$P \xrightarrow{\bar{a}}_a Q \text{ iff } P \approx_1 Q.$$

The following lemma relates the translation-based and the run-time proof techniques.

Lemma 6.3 *Let P and Q be two processes in $L\pi$. Then:*

$$P \approx_1 Q \text{ iff } \llbracket P \rrbracket \simeq_a \llbracket Q \rrbracket.$$

Proof: We give a sketch of the proof. A detailed proof can be found in Appendix A.2. In the implication from left to right, we use a variant of the operational correspondence between processes P and $\llbracket P \rrbracket$ to show that the relation

$$\mathcal{S} = \{(\llbracket P \rrbracket, \llbracket Q \rrbracket) \mid P, Q \in L\pi \text{ and } P \approx_1 Q\}$$

is a \simeq_a -bisimulation up-to \gtrsim and \approx . In the implication from right to left, we show that the relation

$$\mathcal{S} = \{(P, Q) \mid P, Q \in L\pi \text{ and } \llbracket P \rrbracket \simeq_a \llbracket Q \rrbracket\}$$

is a link bisimulation. \square

Finally, we prove the soundness of the “run-time” proof technique.

Theorem 6.4 (Soundness) *Let P and Q be two processes in $L\pi$. Then*

$$P \xrightarrow{\bar{a}}_a Q \text{ implies } P \cong_{L\pi} Q.$$

Proof: By applying, in sequence, Lemma 6.2, Lemma 6.3, and Theorem 5.14. \square

Both the “translation-based” and the “run-time” proof techniques are based on the use of links. In the former, links are added statically via an encoding (at “compile-time”); in the latter, they are added dynamically in the bisimulation game (at “run-time”). The advantages of the latter proof-technique are that: (i) it uses simpler links $p \triangleright b$ instead of links $p \rightarrow b$; (ii) links are not added in case of internal communications; (iii) the input clause uses the particle $\bar{a}b$ instead of $\llbracket \bar{a}b \rrbracket$ (that produces links); (iv) in the latter proof technique, the number of added links may be further reduced using the *up to link* proof technique (see Section 8).

7 Two characterisations of barbed congruence

In this section we show that the translation-based and the run-time proof techniques mentioned above are not only sound but also complete, that is, they completely characterise barbed congruence in $L\pi$. As usual when proving labelled characterisations of barbed congruence [3, 46], we prove the completeness for image-finite processes (see Definition 3.2). The challenge here is that, unlike similar results in the literature, our calculus does not provide any construct for testing equality between names (such as matching).

Lemma 7.1 *Let P and Q be two image-finite $L\pi$ -processes. Then*

$$P \cong_{L\pi} Q \text{ implies } P \approx_1 Q.$$

Proof: Let \simeq_1 be the variant of \approx_1 obtained by replacing $\xrightarrow{\mu}$ with $\xRightarrow{\mu}$ in the hypothesis of each clause in Definition 5.6. Let $\dot{\simeq}$ be the variant of $\dot{\approx}$ obtained by replacing $\xrightarrow{\tau}$ with $\xRightarrow{\tau}$ and \downarrow_a with \Downarrow_a in the hypothesis of each clause in Definition 3.1. It holds that $\simeq_1 = \approx_1$ and $\dot{\simeq} = \dot{\approx}$. So, we prove that

$$(\forall R \in L\pi \ P \mid R \dot{\simeq} Q \mid R) \implies P \simeq_1 Q.$$

Let \mathcal{F} be the monotone operator over $\mathcal{P}(L\pi \times L\pi)$ associated with the definition of \simeq_1 . Suppose $\simeq_1^0 = L\pi \times L\pi$, $\simeq_1^{k+1} = \mathcal{F}(\simeq_1^k)$, and $\simeq_1^\omega = \bigcap_{k < \omega} \simeq_1^k$. On image-finite LTS the operator \mathcal{F} preserves co-directed sets (the dual of directed sets). In particular, $\mathcal{F}(\simeq_1^\omega) = \simeq_1^\omega$. This means that on image-finite processes $\simeq_1 = \simeq_1^\omega$. Therefore, we are left with proving:

$$(\forall R \in L\pi \ P \mid R \dot{\simeq} Q \mid R) \text{ imply that } P \simeq_1^\omega Q.$$

We define a collection of tests $R(n, \mathcal{L}, \mathcal{M})$ depending on the integer n and the finite sets of channel names \mathcal{L}, \mathcal{M} . Intuitively, \mathcal{L} contains the free names along which the processes P and Q may perform some observable actions which have to be tested by $R(n, \mathcal{L}, \mathcal{M})$; \mathcal{M} contains the names in \mathcal{L} which cannot be used in input subject position by the test process. We show by induction on n that there exist $\mathcal{L}, \mathcal{M}, \mathcal{L}'$ such that $\mathcal{L} \supseteq \text{fn}(P, Q)$, $\mathcal{L}' \subseteq \mathcal{L}$, $\mathcal{M} \subseteq \mathcal{L}$ and $(\nu \mathcal{L}')(P \mid R(n, \mathcal{L}, \mathcal{M})) \dot{\simeq} (\nu \mathcal{L}')(P \mid R(n, \mathcal{L}, \mathcal{M}))$ implies $P \simeq_1^n Q$.

If the property above holds then we can conclude the proof by observing that:

$$\begin{aligned} \forall R \in L\pi \ (P \mid R \dot{\simeq} Q \mid R) \text{ implies } (\nu \mathcal{L}')(P \mid R(n, \mathcal{L}, \mathcal{M})) \dot{\simeq} (\nu \mathcal{L}')(Q \mid R(n, \mathcal{L}, \mathcal{M})) \\ \text{for each } n \in \omega \text{ with } \mathcal{L} = \text{fn}(P, Q), \\ \mathcal{M} = \emptyset, \text{ and } \mathcal{L}' = \emptyset. \\ \text{implies } \forall n \in \omega \ P \simeq_1^n Q \\ \text{implies } P \simeq_1^\omega Q \\ \text{implies } P \simeq_1 Q. \end{aligned}$$

For defining the tests $R(n, \mathcal{L}, \mathcal{M})$ we introduce an internal choice operator \oplus . This is a derived operator defined as follows:

$$P_1 \oplus \dots \oplus P_n \stackrel{\text{def}}{=} (\nu a)(a.P_1 \mid \dots \mid a.P_n \mid \bar{a}) \text{ with } a \notin \text{fn}(P_1, \dots, P_n)$$

We suppose that the collection of channel names Ch has been partitioned in two infinite ordered sets Ch' and Ch'' . In the following we have $\mathcal{L}' \subseteq \mathcal{L}$, $\mathcal{M} \subseteq \mathcal{L}$, $\mathcal{L} \subseteq Ch''$. We also use the sequences

$$\{b_n, b'_n : n \in \omega\} \cup \{c_n^\beta : n \in \omega, \beta \in \{\tau, a, \bar{a} : a \in Ch''\}\}$$

of distinct names in Ch' . The test $R(n, \mathcal{L}, \mathcal{M})$ is defined by induction on n as follows, where we pick a' to be the first name in the ordered set $Ch'' \setminus \mathcal{L}$. When emitting or receiving a name which is not in \mathcal{L} we work up to injective substitution to show that $P \simeq_1^n Q$. The relation $R(n, \mathcal{L}, \mathcal{M})$ is defined as follows:

$$R(0, \mathcal{L}, \mathcal{M}) = \bar{b}_0 \oplus \bar{b}'_0$$

$$\begin{aligned}
R(n, \mathcal{L}) &= \overline{b}_n \oplus \overline{b}'_n \text{ (for } n > 0) \\
&\oplus (\overline{c}_n \oplus R(n-1, \mathcal{L}, \mathcal{M})) \\
&\oplus \{\overline{c}_n \oplus ((\nu a')(\overline{a}a' \mid R(n-1, \mathcal{L} \cup \{a'\}, \mathcal{M}))) \mid a \in \mathcal{L}\} \\
&\oplus \{\overline{c}_n \oplus a(x). (a' \triangleright x \mid R(n-1, \mathcal{L} \cup \{a'\}, \mathcal{M} \cup \{a'\})) \mid a \in \mathcal{L}, a \notin \mathcal{M}\}.
\end{aligned}$$

The proof is by induction on n . Details can be found in Appendix A.3. \square

By Lemma 7.1 we can derive the completeness of our two proof techniques.

Theorem 7.2 (First characterisation) *Let P and Q be two processes in $L\pi$. Then:*

1. $P \cong_{L\pi} Q$ implies $\llbracket P \rrbracket \succ_a \llbracket Q \rrbracket$, for P and Q image-finite;
2. $\llbracket P \rrbracket \succ_a \llbracket Q \rrbracket$ implies $P \cong_{L\pi} Q$.

Proof: Part 1 follows by applying in sequence Lemmas 7.1 and 6.3. Part 2 follows from Theorem 5.14 \square

Our translation based proof technique relies on the algebraic law

$$\overline{a}b \cong_{L\pi} (\nu c)(\overline{a}c \mid c \rightarrow b) \quad (7)$$

As already pointed out in Section 5, a simpler translation $\llbracket \cdot \rrbracket$ can be defined by replacing this law with:

$$\overline{a}b \cong_{L\pi} (\nu c)(\overline{a}c \mid c \triangleright b) \quad (8)$$

(we recall that $c \triangleright b \stackrel{\text{def}}{=} !c(x).\overline{b}x$). The encoding $\llbracket \cdot \rrbracket$ obtained by using Law 8 instead of 7 is still sound but it *is not* complete. As a counterexample, take the processes:

$$\begin{aligned}
P &\stackrel{\text{def}}{=} \overline{a}b \\
Q &\stackrel{\text{def}}{=} (\nu c)(\overline{a}c \mid c \rightarrow b) = (\nu c)(\overline{a}c \mid !c(x).(\nu d)(\overline{b}d \mid d \rightarrow x)).
\end{aligned}$$

Then, $P \cong_{L\pi} Q$ whereas $\llbracket P \rrbracket$ and $\llbracket Q \rrbracket$ are not related by either \succ_a or \approx . Indeed,

$$\begin{aligned}
\llbracket P \rrbracket &\stackrel{\text{def}}{=} (\nu h)(\overline{a}h \mid !h(x).\overline{b}x) \\
\llbracket Q \rrbracket &\stackrel{\text{def}}{=} (\nu c)((\nu h)(\overline{a}h \mid !h(x).\overline{c}x) \mid !c(x).(\nu d)((\nu r)(\overline{b}r \mid !r(x).\overline{d}x) \mid \llbracket d \rightarrow x \rrbracket)).
\end{aligned}$$

and both relations \succ_a and \approx can distinguish the two processes after performing two visible actions.

More precisely, $\llbracket P \rrbracket \xrightarrow{\overline{a}(h)} \xrightarrow{h(s)} \overline{b}s$ whereas $\llbracket Q \rrbracket \xrightarrow{\overline{a}(h)} \xrightarrow{h(s)} \overline{b}(r)$.

Theorem 7.3 (Second characterisation) *Let P and Q be two processes in $L\pi$. Then:*

1. $P \cong_{L\pi} Q$ implies $P \overset{\rightarrow}{\approx}_a Q$, for P and Q image-finite processes;
2. $P \overset{\rightarrow}{\approx}_a Q$ implies $P \cong_{L\pi} Q$.

Proof: Part 1 follows by applying in sequence Lemmas 7.1 and 6.2. Part 2 follows from Theorem 6.4. \square

Theorem 7.3 says that, on image-finite processes, asynchronous ground bisimilarity, defined on the new LTS, coincides with barbed congruence in $L\pi$. We recall that, in presence of matching, the closure under substitutions of asynchronous early bisimilarity on the LTS $\xrightarrow{\mu}$ coincides with barbed congruence in π_a [3]. Therefore, somehow, the difference between the two LTSs essentially shows the difference between what is observable in $L\pi$ and what is observable in π_a with matching.

8 Up-to link proof techniques

As for standard bisimilarity, link bisimilarity can be enhanced by means of up to expansion techniques [55].

Definition 8.1 (Link bisimilarity up to expansion) *A symmetric relation S on $L\pi$ -processes is a link bisimulation up to \gtrsim if whenever $P S Q$ the following holds:*

1. If $P \xrightarrow{\tau} P'$, then $Q \Longrightarrow Q'$ and $P' \gtrsim S \lesssim Q'$.
2. If $P \xrightarrow{a(p)} P'$, and $p \notin \text{fn}(Q)$, then
 - (a) either $Q \xrightarrow{a(p)} Q'$ and $P' \gtrsim S \lesssim Q'$
 - (b) or $Q \Longrightarrow Q'$ and $P' \gtrsim S \lesssim (Q' \mid \bar{a}p)$.
3. If $P \xrightarrow{\bar{a}b} P'$, and $p \notin \text{fn}(P, Q)$, then
 - (a) either $Q \xrightarrow{\bar{a}d} Q'$ and $(p \triangleright b \mid P') \gtrsim S \lesssim (p \triangleright d \mid Q')$
 - (b) or $Q \xrightarrow{\bar{a}(c)} Q'$, with $c \notin \text{fn}(P)$, and $(p \triangleright b \mid P') \gtrsim S \lesssim (\nu c)(p \triangleright c \mid Q')$.
4. If $P \xrightarrow{\bar{a}(c)} P'$, with $c \notin \text{fn}(Q)$ and $p \notin \text{fn}(P, Q)$, then
 - (a) either $Q \xrightarrow{\bar{a}b} Q'$ and $(\nu c)(p \triangleright c \mid P') \gtrsim S \lesssim (p \triangleright b \mid Q')$
 - (b) or $Q \xrightarrow{\bar{a}(c)} Q'$ and $(\nu c)(p \triangleright c \mid P') \gtrsim S \lesssim (\nu c)(p \triangleright c \mid Q')$.

Lemma 8.2 *If S is a link bisimilarity up to expansion then $S \subseteq \approx_1$.*

Proof: The proof is analogous to that of standard bisimilarity [55]. \square

Link bisimilarity can be strengthened by means of a more powerful up-to proof technique which allows us to reduce the number of links introduced in the derivatives. Roughly speaking, when comparing two processes P and Q this technique permits cutting the *same* links from both processes, or to cut a *private* link from one process only.

Definition 8.3 (Link bisimulation up to link) *A symmetric relation S on $L\pi$ -processes is a link bisimulation up to link if whenever $P S Q$ the following holds:*

1. If $P \xrightarrow{\tau} P'$ then $Q \Longrightarrow Q'$ and $P' S Q'$.
2. If $P \xrightarrow{a(p)} P'$, and $p \notin \text{fn}(Q)$, then
 - (a) either $Q \xrightarrow{a(p)} Q'$ and $P' S Q'$
 - (b) or $Q \Longrightarrow Q'$ and $P' S (Q' \mid \bar{a}p)$.
3. If $P \xrightarrow{\bar{a}b} P'$, and $p \notin \text{fn}(P, Q)$, then
 - (a) either $Q \xrightarrow{\bar{a}b} Q'$ and $P' S Q'$
 - (b) or $Q \xrightarrow{\bar{a}d} Q'$, with $d \neq b$, and $(p \triangleright b \mid P') S (p \triangleright d \mid Q')$
 - (c) or $Q \xrightarrow{\bar{a}(c)} Q'$, with $c \notin \text{fn}(P)$, and
 - i. either $(p \triangleright b \mid P') S Q'\{p/c\}$
 - ii. or $(p \triangleright b \mid P') S (\nu c)(p \triangleright c \mid Q')$.

4. If $P \xrightarrow{\bar{a}(c)} P'$, with $c \notin \text{fn}(Q)$ and $p \notin \text{fn}(P, Q)$, then

- (a) either $Q \xrightarrow{\bar{a}b} Q'$ and
 - i. either $P' \{p/c\} \mathcal{S} (p \triangleright b \mid Q')$
 - ii. or $(\nu c)(p \triangleright c \mid P') \mathcal{S} (p \triangleright b \mid Q')$
- (b) or $Q \xrightarrow{\bar{a}(c)} Q'$ and
 - i. either $P' \mathcal{S} Q'$
 - ii. or $P' \{p/c\} \mathcal{S} (\nu c)(p \triangleright c \mid Q')$
 - iii. or $(\nu c)(p \triangleright c \mid P') \mathcal{S} Q' \{p/c\}$.
 - iv. or $(\nu c)(p \triangleright c \mid P') \mathcal{S} (\nu c)(p \triangleright c \mid Q')$.

Two processes P and Q are link bisimilar up to link, written $P \approx_{\text{lut}} Q$, if $P \mathcal{S} Q$ for some link bisimulation up to link \mathcal{S} .

The up to link technique is inspired by the up to expansion [55] and up to context [47] techniques (in which common contexts are factorised out). However, it cannot be reduced to them because private links may be cut from only one process and not from both of them as required by the up to context technique.

As usual in up-to proof techniques, we need not always apply a cut for reducing the size of the derivative processes. This explains why we have the subclauses marked by *i. . . . iv.*

The proof of the completeness of the up to link technique is non trivial.

Theorem 8.4 *Let P and Q be two $L\pi$ -processes. Then:*

$$P \approx_1 Q \text{ iff } P \approx_{\text{lut}} Q.$$

Proof: We give a sketch of the proof. Details can be found in Appendix A.4. In the implication from left to the right, we prove that the relation

$$\mathcal{S} = \{(P, Q) : P \approx_1 Q\}$$

is a link bisimulation up to link. The only interesting point in the proof is when dealing with the clause in which a free output action $\bar{a}b$ is matched by the same free output action. In this case we need a result (see Lemma A.4) saying that if

$$p \notin \text{fn}(P, Q) \text{ and } (p \triangleright b \mid P) \approx_1 (p \triangleright b \mid Q) \text{ then } P \approx_1 Q.$$

In the implication from right to left we prove that the relation

$$\mathcal{S} = \{(P, Q) : P \approx_{\text{lut}} Q\}$$

is a link bisimulation. The proof requires the following results (see Lemma A.6):

1. $P \approx_{\text{lut}} Q$ and $p \notin \text{fn}(P, Q)$ implies $(p \triangleright b \mid P) \approx_{\text{lut}} (p \triangleright b \mid Q)$.
2. $P \approx_{\text{lut}} Q$ and $p \notin \text{fn}(P, Q)$ implies $(\nu c)(p \triangleright c \mid P) \approx_{\text{lut}} (\nu c)(p \triangleright c \mid Q)$.
3. $P \{p/c\} \approx_{\text{lut}} (\nu c)(p \triangleright c \mid Q)$ and $p \notin \text{fn}(P, Q)$ implies $(\nu c)(p \triangleright c \mid P) \approx_{\text{lut}} (\nu c)(p \triangleright c \mid Q)$.
4. $P \{p/c\} \approx_{\text{lut}} (p \triangleright b \mid Q)$ and $c \notin \text{fn}(Q)$ implies $(\nu c)(p \triangleright c \mid P) \approx_{\text{lut}} (p \triangleright b \mid Q)$.

□

The up to link technique can be used in combination with up to expansion and up to context techniques.

9 Applications of the theory of Localised π

In this section we show a certain number of applications of the theory of $L\pi$.

9.1 Expressing substitution in $L\pi$

In π -calculus, the process $P\{b/a\}$ can be expressed as $(\nu u)(\bar{u}b \mid u(a).P)$. In $L\pi$, there exists an alternative way to express name substitution which presents a few advantages (see Sections 9.5 and 9.7, and [29]).

Proposition 9.1 *Let P be an $L\pi$ -process and a and b two names such that $a \neq b$ and a does not appear free in P in input position. Then:*

$$(\nu a)(P \mid a \triangleright b) \cong_{L\pi} P\{b/a\}.$$

Proof: We code up, via $\llbracket \cdot \rrbracket$ (the encoding in Section 5), both members. By Lemma 5.2 we get

$$\llbracket (\nu a)(P \mid a \triangleright b) \rrbracket = (\nu a)(\llbracket P \rrbracket \mid a \rightarrow b) \succeq \llbracket P \rrbracket\{b/a\} = \llbracket P\{b/a\} \rrbracket.$$

Since \succeq implies \approx , we use Corollary 5.15 to conclude. \square

The law in Proposition 9.1 is valid in $L\pi$ but not in π_a and π -calculus. A similar law, but with the double link $a \triangleright b \mid b \triangleright a$ in place of $a \triangleright b$, is given in [24] for the asynchronous π -calculus.

We exploit Proposition 9.1 to give an easy proof that early and ground link bisimilarities coincide in $L\pi$. We denote with \approx_1^e the early variant of \approx_1 , obtained by replacing input clause in Definition 6.1 with

2. $P \xrightarrow{a(x)} P'$ implies that for all b , there exists Q' such that:

- (a) either $Q \xrightarrow{a(x)} Q'$ and $P'\{b/x\} \mathcal{S} Q'\{b/x\}$
- (b) or $Q \Longrightarrow Q'$ and $P'\{b/x\} \mathcal{S} (Q' \mid \bar{a}b)$.

Proposition 9.2 $P \approx_1^e Q$ iff $P \approx_1 Q$.

Proof: The implication from left to right is easy. An early bisimilarity has a universal quantification on the received names, whereas a ground bisimilarity has an existential quantification. Hence an early bisimilarity is included in its ground variant. For the implication from right to left, we prove that the relation

$$\mathcal{S} = \{(P, Q) : P, Q \in L\pi, P \approx_1 Q\}$$

is an early link bisimulation. We focus on the input clause because this is the only difference between the two bisimilarities. Suppose $P \xrightarrow{a(x)} P'$. We want to prove that for every b there exists Q' such that $Q \xrightarrow{a(x)} Q'$ and $P'\{b/x\} \mathcal{S} Q'\{b/x\}$. The case $b = x$ is trivial, so we suppose $b \neq x$. Since $P \approx_1 Q$, there exists Q' such that $Q \xrightarrow{a(x)} Q'$ and $P' \approx_1 Q'$. Notice that, since P' and Q' are $L\pi$ -processes, x does not appear free in P' and Q' in input subject position. By Lemma 6.3, and Corollary 5.13 link bisimilarity is an equivalence relation and it is preserved by all operators of the calculus. So, $(\nu x)(P' \mid x \triangleright b) \approx_1 (\nu x)(Q' \mid x \triangleright b)$ for every name b . By Lemma 5.2 and Lemma 6.3 it holds that $P'\{b/x\} \approx_1 (\nu x)(P' \mid x \triangleright b)$ and $Q'\{b/x\} \approx_1 (\nu x)(Q' \mid x \triangleright b)$. By transitivity we have that $P'\{b/x\} \approx_1 Q'\{b/x\}$ and therefore $P'\{b/x\} \mathcal{S} Q'\{b/x\}$. \square

9.2 The replication theorems

The *replication theorems* [31] express useful distributivity properties of private replicated processes. The assertions of the theorems can be read thus: A passive resource that is shared among a certain number of clients can be made private to each of them.

Theorem 9.3 (Standard replication theorems) *Assume that name a occurs free in processes P , Q and R only in output subject position. Then:*

1. $(\nu a)(!a(x).R \mid P \mid Q) \approx (\nu x)(!a(x).R \mid P) \mid (\nu a)(!a(x).R \mid Q)$.
2. $(\nu a)(!a(x).R \mid !P) \approx !(\nu a)(!a(x).R \mid P)$.

The side condition in the theorems prevents the restricted name a from being exported. As a consequence, the theorem cannot be used in situations where the set of clients of the resource $a(x).R$ may change dynamically. To see why this side condition is necessary, take:

$$\begin{aligned} P_1 &\stackrel{\text{def}}{=} (\nu a)(!a(x).R \mid \bar{b}a \mid Q) \\ P_2 &\stackrel{\text{def}}{=} (\nu a)(!a(x).R \mid \bar{b}a) \mid (\nu a)(!a(x).R \mid Q) \end{aligned}$$

These processes are in general not equivalent in π -calculus. Intuitively, the environment external to P_1 can receive a along b and then use it in input position to interfere with an attempt by Q to activate a copy of R . This is not possible in P_2 , where Q has its own private access to R . The difference between P_1 and P_2 can be observed in a context that receives a and then uses it in input; in this way, the context may steal messages that were supposed to reach the resource.

Pierce and Sangiorgi [43] have shown that the side condition can be relaxed using the type system with input/output capabilities, and requiring that the processes R , P and Q only possess the output capability on a . The same result is proved in [52] by previously translating processes (by means of an encoding very close to our $[\cdot]$) and then proving that the image are bisimilar. In both cases the sharpened replication theorems are shown valid with respect to (typed) barbed congruence by proving a few barbed bisimilarities. Here we propose easier proofs of the sharpened replication theorems without using typed bisimulations. While the results in [43, 52] are for the (standard) π -calculus, our results only apply to $L\pi$.

Theorem 9.4 (sharpened replication theorems) *Let P , Q , and R be processes in $L\pi$ not containing name a in input position. Then:*

1. $(\nu a)(!a(x).R \mid P \mid Q) \cong_{L\pi} (\nu x)(!a(x).R \mid P) \mid (\nu a)(!a(x).R \mid Q)$;
2. $(\nu a)(!a(x).R \mid !P) \cong_{L\pi} !(\nu a)(!a(x).R \mid P)$.

Proof: We code up, via $[\cdot]$, both members of each equation. By definition of $[\cdot]$ name a may appear free in the translated terms only in output subject position. Therefore, the translated terms comply with the hypotheses of Theorem 9.3 and we can assert that the images (of each equation) are synchronous ground bisimilar. Since \approx implies \succ_a , by theorem 5.14 we can conclude. \square

The replication theorems have been proved in [31, 43] with respect to a *strong* form of bisimilarity which is sensitive to τ -actions. This strong form of bisimilarity implies \approx . On the other hand, Theorem 9.4 is proved with respect to a weak version of barbed congruence. Our proof cannot be adapted to strong barbed congruence because we rely on the encoding $[\cdot]$ which does not preserve the number of τ -actions performed by a process.

9.3 The delayed input

In an asynchronous calculus message emission is non-blocking. Milner, Parrow, Victor and others have advocated also non-blocking message reception (which is among the motivations for the Update and the Fusion calculi [40, 41] and for the Chi calculus [18]). Such a *delayed input*,

$\text{d-in: } \frac{}{a(b)P \xrightarrow{a(b)} P}$	$\text{s-com: } \frac{P \xrightarrow{\bar{a}c} P'}{a(b)P \xrightarrow{\tau} (\nu b)(P'\{c/b\})}$
$\text{p-in: } \frac{P \xrightarrow{\mu} P' \quad b \notin \text{fn}(\mu) \quad a \notin \text{bn}(\mu)}{a(b)P \xrightarrow{\mu} a(b)P'}$	$\text{s-cls: } \frac{P \xrightarrow{\beta_c \bar{a}c} P' \quad b \notin \text{fn}(\beta_c \bar{a}c)}{a(b)P \xrightarrow{\tau} \beta_c(P'\{c/b\})}$
$\text{o-}\nu: \frac{P \xrightarrow{\mu} P' \quad [\mu = \bar{a}c \vee \mu = c(b)\bar{a}b] \quad a \neq c}{(\nu c)P \xrightarrow{(\nu c)\mu} P'}$	$\text{o-in: } \frac{P \xrightarrow{\bar{a}b} P' \quad b \neq a}{c(b)P \xrightarrow{c(b)\bar{a}b} P'}$
$\text{cls: } \frac{P \xrightarrow{\beta_c \bar{a}c} P' \quad Q \xrightarrow{a(b)} Q' \quad \text{bn}(\beta_c) \cap \text{fn}(Q) = \emptyset}{P \mid Q \xrightarrow{\tau} \beta_c(P' \mid Q'\{c/b\})}$	

Table 4: New transition rules, for delayed input

written $a(x)P$, should allow the continuation P to evolve underneath the input guard, except for observable actions along x . The delayed input replaces *temporal precedencies*, imposed by plain input, with *causal dependencies*. This appears, for instance, in Abramsky's representation of Linear Logic proofs as π -calculus processes [1, 6]. Non-blocking message reception has been considered by Bellin and Scott [6], Boudol [11], Fu [18], Parrow and Victor [41], Yoshida [62] and van Breugel [58]. Bellin and Scott give a reduction semantics for a version of π -calculus, proposed by Milner, where both message emission and message reception are non-blocking [32]; van Breugel defines a labelled transition system for such calculus and proves a correspondence with Bellin and Scott's reduction semantics.

Let $\text{DL}\pi$ be the calculus obtained by adding the delayed input construct $a(b)P$ to the grammar of $\text{L}\pi$ (with the same constraint as plain input that b may not appear free in P in input position). Actions are extended as follows:

$$\mu ::= \tau \mid a(b) \mid \bar{a}b \mid \beta_b \bar{a}b$$

where

$$\beta_b ::= (\nu b) \mid c(b) \mid (\nu c)c(b) \text{ for some } c.$$

β_b represents the binding part of bound output actions. We extend free and bound names as follows: $\text{fn}((\nu b)\bar{a}b) = \{a\}$, $\text{bn}((\nu b)\bar{a}b) = \{b\}$, $\text{fn}(c(b)\bar{a}b) = \{c, a\}$, $\text{bn}(c(b)\bar{a}b) = \{b\}$, $\text{fn}(\nu c)c(b)\bar{a}b = \{a\}$, $\text{bn}(\nu c)c(b)\bar{a}b = \{c, b\}$. In Table 4, we give the missing transition rules of $\text{DL}\pi$. More precisely, we enrich the rules in Table 1 as follows: (i) rule `close` is split into rules `cls` and `s-cls`; (ii) rule `open` is split into rules `o-in` and `o-ν`; (iii) the rules `d-inp`, `s-com`, and `p-inp` are similar to the rules `inp`, `com`, and `par`, but involve the delayed input. Our labelled transition system has two main differences with respect to that of van Breugel's [58]: (i) actions have a simpler syntax, because only the output capability of name may be transmitted; (ii) a restriction (νb) is added in rule `s-com` to model *self communications*, as in $a(b)(\bar{a}b \mid P) \xrightarrow{\tau} (\nu b)P$.

We prove that the delayed input is a derived operator in $\text{L}\pi$.

In Table 5 we give an encoding $\{\cdot\}$ of $\text{DL}\pi$ into $\text{L}\pi$ and prove that it is fully-abstract with respect to barbed congruence. The encoding $\{\cdot\}$ is an homomorphism on all operators except delayed input. (A similar encoding, but with the double link $b \triangleright b' \mid b' \triangleright b$ in place of $b \triangleright b'$, has been suggested by Yoshida in [62] for the asynchronous π -calculus.)

In order to prove the full abstraction of $\{\cdot\}$, we first prove an adequacy result with respect to barbed bisimulation. The proof of this adequacy result requires an operational correspondence

$$\begin{array}{lll}
\{P_1 \mid P_2\} \stackrel{\text{def}}{=} \{P_1\} \mid \{P_2\} & \{(\nu a)P\} \stackrel{\text{def}}{=} (\nu a)\{P\} & \{\bar{a}b\} \stackrel{\text{def}}{=} \bar{a}b \\
\{a(b).P\} \stackrel{\text{def}}{=} a(b).\{P\} & \{!a(b).P\} \stackrel{\text{def}}{=} !a(b).\{P\} & \{\mathbf{0}\} \stackrel{\text{def}}{=} \mathbf{0} \\
\{a(b)P\} \stackrel{\text{def}}{=} (\nu b)(a(b').b \triangleright b' \mid \{P\})
\end{array}$$

Table 5: The encoding $\{\cdot\}$

between processes P and $\{P\}$, up to some notion of expansion. As we will argue in Remark 9.11, such an operational correspondence is not easy to prove. Thus, for convenience, we define an auxiliary encoding $\llbracket \cdot \rrbracket$ as the composition of the encodings $\{\cdot\}$ and $\llbracket \cdot \rrbracket$ (of Section 5). Precisely, if P is a $\text{DL}\pi$ -process

$$\llbracket P \rrbracket \stackrel{\text{def}}{=} \{\{P\}\}.$$

We prove that the encoding $\llbracket \cdot \rrbracket$ satisfies an operational correspondence up to \succcurlyeq_a , where \preccurlyeq_a denotes the expansion variant of \preccurlyeq_a (Definition 5.6) in the same way as \lesssim_a denotes the expansion variant of \approx_a (see Definition 3.5). This operational correspondence, together with Theorem 5.3, allows us to prove the soundness of $\{\cdot\}$. Then, by exploiting the inclusion $\text{L}\pi \subset \text{DL}\pi$ we prove the completeness of $\{\cdot\}$.

For proving the operational correspondence of $\llbracket \cdot \rrbracket$ we need to know that \preccurlyeq_a is a precongruence in $\mathcal{L}\pi$ (simply adapt Corollary 5.13). We also need the following technical lemma.

Lemma 9.5 *Given an $\text{L}\pi$ -process P and a name a it holds that*

$$(\nu a)(a \rightarrow a \mid \llbracket P \rrbracket) \succcurlyeq_a (\nu a)\llbracket P \rrbracket.$$

Proof: We have $a \rightarrow a \succcurlyeq_a \mathbf{0}$. Then we can conclude because \succcurlyeq_a is a precongruence. \square

Lemma 9.6 (Operational correspondence of $\llbracket \cdot \rrbracket$) *Let P be a process in $\text{DL}\pi$.*

1. *Suppose that $P \xrightarrow{\mu} P'$. Then we have:*

- (a) *if $\mu = a(b)$ then $\llbracket P \rrbracket \xrightarrow{a(b')} \succcurlyeq \llbracket P' \rrbracket \{b'/b\}$ and $b' \notin \text{fn}(P)$*
- (b) *if $\mu = \bar{a}b$ then $\llbracket P \rrbracket \xrightarrow{(\nu c)\bar{a}c} \succcurlyeq_a (c \rightarrow b \mid \llbracket P' \rrbracket)$, with $c \notin \text{fn}(P)$*
- (c) *if $\mu = (\nu b)\bar{a}b$ then $\llbracket P \rrbracket \xrightarrow{(\nu c)\bar{a}c} \succcurlyeq_a (\nu b)(c \rightarrow b \mid \llbracket P' \rrbracket)$, with $c \notin \text{fn}(P)$*
- (d) *if $\mu = d(b)\bar{a}b$ then $\llbracket P \rrbracket \xrightarrow{(\nu c)\bar{a}c} \succcurlyeq_a (\nu b)(d(b').b \rightarrow b' \mid c \rightarrow b \mid \llbracket P' \rrbracket)$, with $\{b', c\} \cap \text{fn}(P) = \emptyset$*
- (e) *if $\mu = (\nu d)d(b)\bar{a}b$ then $\llbracket P \rrbracket \xrightarrow{(\nu c)\bar{a}c} \succcurlyeq_a (\nu b)(\nu d)(d(b').b \rightarrow b' \mid c \rightarrow b \mid \llbracket P' \rrbracket)$, with $\{b', c\} \cap \text{fn}(P) = \emptyset$*
- (f) *if $\mu = \tau$ then $\llbracket P \rrbracket \xrightarrow{\tau} \succcurlyeq_a \llbracket P' \rrbracket$.*

2. *Suppose that $\llbracket P \rrbracket \xrightarrow{\mu} P_1$. Then there exists $P' \in \text{DL}\pi$ such that:*

- (a) *if $\mu = a(b)$ then $P \xrightarrow{a(b)} P'$ and $P_1 \succcurlyeq_a \llbracket P' \rrbracket \{b'/b\}$*

(b) if $\mu = (\nu c)\bar{a}c$ then:

- i. either $P \xrightarrow{\bar{a}b} P'$ and $P_1 \succ_a (c \rightarrow b \mid \llbracket P' \rrbracket)$, with $c \notin \text{fn}(P)$
- ii. or $P \xrightarrow{(\nu b)\bar{a}b} P'$ and $P_1 \succ_a (\nu b)(c \rightarrow b \mid \llbracket P' \rrbracket)$, with $c \notin \text{fn}(P)$
- iii. or $P \xrightarrow{d(b)\bar{a}b} P'$ and $P_1 \succ_a (\nu b)(d(b'). b \rightarrow b' \mid c \rightarrow b \mid \llbracket P' \rrbracket)$,
with $\{b', c\} \cap \text{fn}(P) = \emptyset$
- iv. or $P \xrightarrow{(\nu d)d(b)\bar{a}b} P'$ and $P_1 \succ_a (\nu b)(\nu d)(d(b'). b \rightarrow b' \mid c \rightarrow b \mid \llbracket P' \rrbracket)$,
with $\{b', c\} \cap \text{fn}(P) = \emptyset$

(c) if $\mu = \tau$ then $P \xrightarrow{\tau} P'$ with $P_1 \succ_a \llbracket P' \rrbracket$.

Proof: By transition induction. The proof relies on Proposition 4.3(2), Lemma 5.2, and Lemma 9.5. Details can be found in Appendix A.5. \square

From Lemma 9.6 we can derive a weak operational correspondence.

Lemma 9.7

- 1. If $P \Longrightarrow P'$ then $\llbracket P \rrbracket \Longrightarrow_{\succ_a} \llbracket P' \rrbracket$.
- 2. If $\llbracket P \rrbracket \Longrightarrow P_1$ then there is P' such that $P \Longrightarrow P'$ and $P_1 \succ_a \llbracket P' \rrbracket$.
- 3. $P \Downarrow_a$ iff $\llbracket P \rrbracket \Downarrow_a$.

Proof: Parts 1 and 2 are proven by induction on the number of τ -moves by exploiting Lemma 9.6. Part 3 is a consequence of parts 1 and 2, and Lemma 9.6. \square

Lemma 9.7 allows us to prove that the encoding $\llbracket \cdot \rrbracket$ is adequate with respect to barbed bisimulation.

Lemma 9.8 *Let P and Q be two processes in $\text{DL}\pi$. Then:*

$$P \dot{\approx} Q \text{ iff } \llbracket P \rrbracket \dot{\approx} \llbracket Q \rrbracket.$$

Proof: In the implication from left to right, we use Lemma 9.7 to prove that the relation $\mathcal{R} = \{(\llbracket P \rrbracket, \llbracket Q \rrbracket) : P \dot{\approx} Q\}$ is a barbed bisimulation up-to \succ_a . In the implication from right to left we use Lemma 9.7 and the fact that $\lesssim_a \dot{\approx} \succ_a \subset \dot{\approx}$ to prove that the relation $\mathcal{R} = \{(P, Q) : \llbracket P \rrbracket \dot{\approx} \llbracket Q \rrbracket\}$ is a barbed bisimulation. \square

Lemma 9.8 allows us to prove that the encoding $\{\cdot\}$ is adequate with respect to barbed bisimulation and therefore sound with respect to barbed congruence.

Lemma 9.9 *Let P and Q be two $\text{DL}\pi$ -processes. Then:*

$$P \dot{\approx} Q \text{ iff } \{P\} \dot{\approx} \{Q\}.$$

Proof: By the definition of $\llbracket \cdot \rrbracket$, Lemma 9.8, and Theorem 5.3. \square

Notice that if $P \in \text{L}\pi$ then $\{P\} = P$. This will allow us to prove the completeness of $\{\cdot\}$.

Theorem 9.10 (Full abstraction of $\{\cdot\}$) *Let P and Q be two processes in $\text{DL}\pi$. Then:*

$$P \cong_{\text{DL}\pi} Q \text{ iff } \{P\} \cong_{\text{L}\pi} \{Q\}.$$

Proof: The soundness follows from Lemma 9.9 and the compositionality of $\{\cdot\}$. As regards the completeness, we want to prove that for every $\text{L}\pi$ -context $C[\cdot]$ it holds that $C[\{P\}] \dot{\approx} C[\{Q\}]$. Let $C[\cdot]$ be a such a context. By the compositionality of $\{\cdot\}$ and the fact that $\{\cdot\}$ does not affect $\text{L}\pi$ -processes, it follows that $\{C[P]\} = C[\{P\}]$ and $\{C[Q]\} = C[\{Q\}]$. Since an $\text{L}\pi$ -context is also a $\text{DL}\pi$ -context, by hypothesis we have $C[P] \dot{\approx} C[Q]$. By Lemma 9.9 this implies $\{C[P]\} \dot{\approx} \{C[Q]\}$. So, we conclude that $C[\{P\}] \dot{\approx} C[\{Q\}]$. \square

Remark 9.11 *In order to clarify the usefulness of the auxiliary encoding $\{\!\!\{\cdot\}\!\!\}$, notice that if one wanted to prove the operational correspondence of $\{\cdot\}$ (instead of $\{\!\!\{\cdot\}\!\!\}$), then Proposition 4.3(2) and Lemma 9.5 would not be necessary anymore. By contrast, an expansion variant of Proposition 9.1 would be necessary. The proof of a such a result would require an expansion variant of Theorem 5.14 (or Corollary 5.15), which, as already pointed out in Remark 5.16, does not hold.*

Using $\{\cdot\}$ and the theory of $L\pi$ we can prove laws for delayed input like:

$$a(b)(P \mid Q) = (a(b)P) \mid Q \quad \text{if } b \notin \text{fn}(Q) \quad (9)$$

$$a(b)c(d)P = c(d)a(b)P \quad \text{if } c \neq b \text{ and } d \neq a \quad (10)$$

$$(\nu a)(a(x)(\bar{a}x \mid P)) = (\nu x)P \quad \text{if } a \notin \text{fn}(P) \quad (11)$$

Laws 9 and 10 are similar to structural rules for restriction. Similar laws have been proposed in [11]. Law 11 transforms a delayed input binder into a restriction binder (it might be interesting to examine delayed input from within action calculi [34]; for instance, law 11 is reminiscent of the definition of restriction in reflexive action calculi [35]).

9.4 Encodings of the λ -calculus

In this example, we use polyadicity, which is straightforward to accommodate in the theory of $L\pi$. We write $\bar{a}\langle b_1 \dots b_n \rangle$ for polyadic outputs and $a(x_1, \dots, x_n)$ for polyadic inputs. Below, we give Milner's encoding of call-by-name λ -calculus into π -calculus (more precisely, the variant in [39]).

$$\begin{aligned} (\lambda x. M \rangle_p &\stackrel{\text{def}}{=} (\nu v)(\bar{p}\langle v \rangle \mid v(x, q). (\lambda M \rangle_q)) \\ (\lambda x \rangle_p &\stackrel{\text{def}}{=} \bar{x}\langle p \rangle \\ (\lambda MN \rangle_p &\stackrel{\text{def}}{=} (\nu q)\left((\lambda M \rangle_q \mid q(v). (\nu x)(\bar{v}\langle x, p \rangle \mid !x(r). (\lambda N \rangle_r))\right) \end{aligned}$$

This is also an encoding into (polyadic) $L\pi$. By applying Proposition 9.1, we can prove the following optimisation of the definition of application in the case when the argument is a variable (a tail-call-like optimisation):

$$(\lambda My \rangle_p \stackrel{\text{def}}{=} (\nu q)\left((\lambda M \rangle_q \mid q(v). \bar{v}\langle y, p \rangle)\right)$$

We can also exploit the delayed input operator, that is a derived operator in $L\pi$, to get an encoding of the *strong* call-by-name strategy, where reductions can also occur underneath an abstraction (i.e., the \mathbf{Xi} rule, saying that if $M \longrightarrow M'$ then $\lambda x. M \longrightarrow \lambda x. M'$, is allowed). For this, we have to relax, in the translation of $\lambda x. M$, the sequentiality imposed by the input prefix $v(x, q)$ that guards the body $(\lambda M \rangle_q$ of the function. Precisely, we have to replace this input with a delayed input:

$$(\lambda x. M \rangle_p \stackrel{\text{def}}{=} (\nu v)(\bar{p}\langle v \rangle \mid v(x, q)(\lambda M \rangle_q)) \quad (12)$$

Using (the polyadic variant of) the encoding of delayed input in Section 9.3, we get:

$$(\lambda x. M \rangle_p \stackrel{\text{def}}{=} (\nu vxq)\left(\bar{p}\langle v \rangle \mid v(y, r). (x \triangleright y \mid q \triangleright r) \mid (\lambda M \rangle_q)\right)$$

Results of operational correspondence and validity of β -reduction, similar to those in [33, 47] for the call-by-name λ -calculus, hold for this encoding. (The modelling of strong reductions is a major motivation behind Fusion and Chi; indeed both calculi allow us to encode strong call-by-name λ -calculus [41, 18].)

$$\begin{aligned} \langle a \langle b \rangle \rangle &\stackrel{\text{def}}{=} \bar{a}b & \langle P \mid Q \rangle &\stackrel{\text{def}}{=} \langle P \rangle \mid \langle Q \rangle \\ \langle \text{def } a \langle x \rangle \mid b \langle y \rangle = P_1 \text{ in } P_2 \rangle &\stackrel{\text{def}}{=} (\nu ab)(!a \langle x \rangle. b \langle y \rangle. \langle P_1 \rangle \mid \langle P_2 \rangle) \end{aligned}$$

Table 6: Mapping of the Join calculus into $L\pi$

9.5 Some properties of the Join calculus

We apply the theory of $L\pi$ to prove some laws in Fournet and Gonthier’s Join calculus [15], a calculus for distributed and concurrent programming.

The Join calculus is an off-spring of the asynchronous π -calculus specifically designed to facilitate distributed implementations of channels mechanisms. The syntax of the (core) Join calculus is given by the following grammar:

$$P ::= a \langle b \rangle \mid P_1 \mid P_2 \mid \text{def } a \langle x \rangle \mid b \langle y \rangle = P_1 \text{ in } P_2.$$

The particle $a \langle b \rangle$ denotes the asynchronous output of name b at channel a . $P_1 \mid P_2$ denotes two processes P_1 and P_2 running in parallel. The construct $\text{def } a \langle x \rangle \mid b \langle y \rangle = P_1 \text{ in } P_2$ is a sort of amalgamation of the operators of replication, parallel composition, and restriction, which allows to model the joint reception of values from different channels.

Free names and *bound names* of a process P , are defined as follows:

- $\text{fn}(a \langle b \rangle) = \{a, b\}$
- $\text{fn}(P_1 \mid P_2) = \text{fn}(P_1) \cup \text{fn}(P_2)$
- $\text{fn}(\text{def } a \langle x \rangle \mid b \langle y \rangle = P_1 \text{ in } P_2) = ((\text{fn}(P_1) \setminus \{x, y\}) \cup \text{fn}(P_2)) \setminus \{a, b\}$.

As for the π -calculus, the operational semantics of the Join calculus can be given in terms of a reduction relation and a relation of structural congruence [28]. With J abbreviating a join pattern $a \langle x \rangle \mid b \langle y \rangle$, the main (simplified) reduction rule is:

$$\text{def } J = P \text{ in } J\sigma \mid Q \rightarrow \text{def } J = P \text{ in } P\sigma \mid Q$$

where the substitution σ does not affect channels a and b .

The intuition is that if an instantiation $J\sigma$ of a definition join-pattern J can be found at top-level in the scope of the definition, then this instance may be replaced by the corresponding instantiation $P\sigma$ of the defined continuation P .

The construct $\text{def } a \langle x \rangle \mid b \langle y \rangle = P_1 \text{ in } P_2$ has the following properties:

1. channels a and b are *locally defined*, that is, they can be accessed only from within P_1 and P_2 ;
2. channels a and b are *uniquely defined*, that is, they appear only in one definition (see also [2, 52]).

A derived construct in Join is the *single pattern definition*

$$\text{def } a \langle x \rangle = P_1 \text{ in } P_2$$

which can be seen as an abbreviation for $\text{def } a \langle x \rangle \mid b \langle y \rangle = P_1 \mid y \langle y \rangle \text{ in } P_2 \mid b \langle b \rangle$, where b is not free in P_1 and P_2 and y is not free in P_1 . Barbed congruence can be defined in Join in the usual manner.

In order to compare the expressivity of Join and π -calculus, Fournet and Gonthier give the encoding reported in Table 6 of the Join calculus into the π -calculus. This encoding, as an encoding of Join into π_a or π -calculus, is not fully-abstract. To obtain full abstraction, Fournet and Gonthier

have to add a layer of “firewalls” to the encoding. We conjecture that the above encoding is fully-abstract with respect to barbed congruence as an encoding of Join into $L\pi$ (a similar conjecture is made by Fournet and Gonthier [15]). It is easy to prove soundness, and this suffices for using the encoding and the theory of $L\pi$ for proving properties of Join processes.

Theorem 9.12 (soundness of $\langle \cdot \rangle$) *Let P and Q be two processes of core Join. Then:*

$$\langle P \rangle \cong_{L\pi} \langle Q \rangle \text{ implies } P \cong_J Q$$

where \cong_J is barbed congruence in core Join.

Proof: The proof follows from the compositionality of the encoding and the operational correspondence between a Join process P and its encoding $\langle P \rangle$. Such an operational correspondence has already been proved in [16]. \square

Using this theorem and the theory of $L\pi$ we can prove the following laws for the Join calculus:

$$\text{def } a\langle x \rangle = R \text{ in } P \mid Q \cong_J (\text{def } a\langle x \rangle = R \text{ in } P) \mid (\text{def } a\langle x \rangle = R \text{ in } Q) \quad (13)$$

$$\text{def } a\langle x \rangle = b\langle x \rangle \text{ in } P \cong_J P\{b/a\} \text{ if } a \neq b \quad (14)$$

$$\text{def } a\langle x \rangle = P \text{ in } (Q \mid a\langle b \rangle) \cong_J \text{def } a\langle x \rangle = P \text{ in } (Q \mid P\{b/x\}) \quad (15)$$

$$\text{def } a\langle x \rangle = P \text{ in } C[a\langle b \rangle] \cong_J \text{def } a\langle x \rangle = P \text{ in } C[P\{b/x\}] \quad (16)$$

where, in (16), context $C[\cdot]$ does not contain binders for a .

Law 13 is the Join calculus version of the replication theorem for parallel composition; it is proved by applying Theorem 9.4(1). Law 14 is the Join calculus version of Proposition 9.1. Law 15 shows a sort of insensitiveness to τ -actions; it is proved in three steps: (i) we apply Theorem 9.4(1), (ii) we use the law $(\nu a)(!a(x). P \mid \bar{a}b) \approx (\nu a)(!a(x). P \mid P\{b/x\})$, (iii) we apply again Theorem 9.4(1). Law 16 is the Join counterpart of Law 3. The proof of Law 16 requires the sharpened replication theorems of Theorem 9.4, plus the laws for pushing replications underneath input prefixes and restrictions. Note that *none* of these laws can be proved from the encoding $\langle \cdot \rangle$ and the theory of π_a or π -calculus: the encodings of the processes in the laws are behaviourally different both in π_a and in π -calculus. In [8], a labelled bisimilarity for the Join is introduced in which the labels of matching transitions must be syntactically the same. As a consequence, this labelled bisimilarity cannot be used to prove laws like 13 and 14.

9.6 External versus internal mobility

The mobility mechanism of π -calculus can be divided into *internal* mobility and *external* mobility [50]. The former arises when an input meets the output of a private name, the latter when an input meets the output of a free name. The πI -calculus is a subcalculus of π , where only private names may be transmitted. The syntax is given by the following grammar:

$$P ::= \mathbf{0} \mid a(x). P \mid (\nu b)(\bar{a}b. P) \mid P \mid P \mid (\nu a)P \mid A\langle a_1, \dots, a_n \rangle$$

In πI , recursive definitions are more appropriate than replication. This because, when only internal mobility is allowed, recursion is strictly more expressive than replication [50]. Each constant A has a unique defining equation of the form $A \stackrel{\text{def}}{=} (\tilde{x})P$. In constant definition $A \stackrel{\text{def}}{=} (\tilde{x})P$ and constant application $A\langle \tilde{a} \rangle$, the parameters \tilde{x} and \tilde{a} are tuples of all distinct names whose length equals the arity of A . In a constant definition $A \stackrel{\text{def}}{=} (\tilde{x})P$ all free occurrences of names \tilde{x} in P are bound and $\text{fn}(P) \subseteq \tilde{x}$. The transition rule for constants is the standard one [36].

Despite the use of only internal mobility, both λ -calculus and higher-order communications can be faithfully encoded in πI .

An asynchronous variant of πI can be defined by replacing, in the grammar, the blocking output processes $(\nu b)(\bar{a}b. P)$ with $(\nu b)(\bar{a}b \mid P)$. We call πI_a this calculus.

In [7], Boreale gives an encoding of asynchronous π -calculus into $\pi\mathbf{I}$. Boreale's encoding is obtained by applying two different encodings one after the other. The former maps the asynchronous π -calculus into $L\pi$; the latter (essentially the encoding $[\cdot]$ of Section 5) maps $L\pi$ into $\pi\mathbf{I}$. Boreale shows that the whole encoding is adequate with respect to barbed bisimilarity by proving the adequacy of the two encodings separately. This result is not quite satisfactory because barbed bisimilarity is a very coarse relation, too coarse to be considered, per se, as an important behavioural equivalence (for instance, it is not even preserved by parallel composition). Boreale leaves as an open problem whether the encoding is fully-abstract for some finer behavioural equivalence. Here, we show that $[\cdot]$ is not fully-abstract as an encoding of $L\pi$ into $\pi\mathbf{I}$. As a counterexample, we take

$$P = a(x).\bar{a}x \text{ and } Q = \mathbf{0}$$

By applying Theorem 5.14, we can show that $P \cong_{L\pi} Q$. However, $\llbracket P \rrbracket \not\approx \llbracket Q \rrbracket$, and since \approx and $\cong_{\pi\mathbf{I}}$ coincides (on image-finite processes [50]) we conclude that $\llbracket P \rrbracket \not\cong_{\pi\mathbf{I}} \llbracket Q \rrbracket$. This negative result is not surprising because the source language is asynchronous while the target language is synchronous. However, even if we considered as target language the asynchronous variant of $\pi\mathbf{I}$, that is $\pi\mathbf{I}_a$, the encoding would not be fully-abstract. As a counterexample, take the same processes P and Q above. Let

$$R \stackrel{\text{def}}{=} (\nu p)(\bar{a}p \mid a(y).(y(z).(\nu q)\bar{z}q \mid (\nu r)(\bar{y}r \mid r(x).(\nu u)\bar{b}u)))$$

be a $\pi\mathbf{I}_a$ -process. Since $\llbracket P \rrbracket = a(x).(\nu d)(\bar{a}d \mid d \rightarrow x)$, the process $\llbracket P \rrbracket \mid R$ would evolve after four τ -steps into the process A where:

$$A \stackrel{\text{def}}{=} (\nu pdr)(d \rightarrow p \mid (\nu h)(\bar{p}h \mid h \rightarrow r) \mid d(z).(\nu q)\bar{z}q \mid r(x).(\nu u)\bar{b}u).$$

It holds that $A \not\Downarrow_b$, while, for all processes B such that $\llbracket Q \rrbracket \mid R \Longrightarrow B$, it holds that $B \Downarrow_b$. We conclude that $\llbracket P \rrbracket \not\cong_{\pi\mathbf{I}_a} \llbracket Q \rrbracket$.

In the remainder of this section we prove that the encoding $[\cdot]$ is fully-abstract when choosing as target calculus the asynchronous variant of $\pi\mathbf{I}$ where only output capability of names may be transmitted. We call *Localised* $\pi\mathbf{I}$, in short $L\pi\mathbf{I}$, this variant of $\pi\mathbf{I}$.

The lemma below will be crucial for proving the desired full abstraction result. We recall that \approx_1 denotes the link bisimilarity of Definition 6.1.

Lemma 9.13 *Let P be a process in $L\pi$. Then $P \approx_1 \llbracket P \rrbracket$.*

Proof: We prove that the relation

$$\mathcal{S} = \{(P, \llbracket P \rrbracket) : P \in L\pi\}$$

is a link bisimulation up to expansion. Let us consider the possible actions of P (we reason in a similar manner when dealing with the possible actions of $\llbracket P \rrbracket$).

1. If $P \xrightarrow{\tau} P'$, by Lemma 5.1, there exists P_1 such that $\llbracket P \rrbracket \xrightarrow{\tau} P_1$ and $P_1 \gtrsim \llbracket P' \rrbracket$. So, $P' \gtrsim P' \mathcal{S} \llbracket P' \rrbracket \lesssim P_1$.
2. If $P \xrightarrow{a(b)} P'$ we reason as in the previous case.
3. If $P \xrightarrow{\bar{a}b} P'$, by Lemma 5.1, P_1 exists such that $\llbracket P \rrbracket \xrightarrow{\bar{a}(c)} P_1$ and $P_1 \gtrsim (c \rightarrow b \mid \llbracket P' \rrbracket)$, with $c \notin \text{fn}(P')$. Since \gtrsim is a congruence, it holds that

$$(\nu c)(p \triangleright c \mid P_1) \gtrsim (\nu c)(p \triangleright c \mid c \rightarrow b \mid \llbracket P' \rrbracket)$$

for p fresh. By Proposition 4.3(3) it holds that

$$p \triangleright b \mid P' \mathcal{S} \llbracket p \triangleright b \mid P' \rrbracket = p \rightarrow b \mid \llbracket P' \rrbracket \lesssim (\nu c)(p \triangleright c \mid P_1).$$

4. If $P \xrightarrow{\bar{\alpha}(b)} P'$, by Lemma 5.1, P_1 exists such that $\llbracket P \rrbracket \xrightarrow{\bar{\alpha}(c)} P_1 \gtrsim (\nu b)(c \rightarrow b \mid \llbracket P' \rrbracket)$ with $c \notin \text{fn}(P')$. By α -conversion there exists P_2 such that

$$\llbracket P \rrbracket \xrightarrow{\bar{\alpha}(b)} P_2 \gtrsim (\nu c)(b \rightarrow c \mid \llbracket P' \rrbracket \{c/b\}).$$

This implies that

$$(\nu b)(p \triangleright b \mid P_2) \gtrsim (\nu b)(p \triangleright b \mid (\nu c)(b \rightarrow c \mid \llbracket P' \rrbracket \{c/b\})).$$

By Proposition 4.3(3) we have

$$(\nu b)(p \triangleright b \mid (\nu c)(b \rightarrow c \mid \llbracket P' \rrbracket \{c/b\})) \gtrsim (\nu c)(p \rightarrow c \mid \llbracket P' \rrbracket \{c/b\}) = (\nu b)(p \rightarrow b \mid \llbracket P' \rrbracket).$$

We conclude by observing that

$$(\nu b)(p \triangleright b \mid P') \mathcal{S} (\nu b)(p \rightarrow b \mid \llbracket P' \rrbracket) \lesssim (\nu b)(p \triangleright b \mid P_2).$$

□

Theorem 9.14 (Full abstraction of $\llbracket \cdot \rrbracket$) *Let P and Q be two processes in $L\pi$. Then:*

$$P \cong_{L\pi} Q \text{ iff } \llbracket P \rrbracket \cong_{L\pi} \llbracket Q \rrbracket.$$

Proof: The implication from right to left follows from Theorem 5.3 and the compositionality of $\llbracket \cdot \rrbracket$. As regards the implication from left to right, we want to prove that for all contexts $C[\cdot]$ in $L\pi$ it holds that $C[\llbracket P \rrbracket] \dot{\approx} C[\llbracket Q \rrbracket]$. By Lemma 9.13 and transitivity of $\cong_{L\pi}$, it follows that $\llbracket P \rrbracket \cong_{L\pi} \llbracket Q \rrbracket$, that is, for all contexts $\hat{C}[\cdot]$ in $L\pi$ it holds that $\hat{C}[\llbracket P \rrbracket] \dot{\approx} \hat{C}[\llbracket Q \rrbracket]$. With a reasoning similar to that in Section 4, it is possible to show that for each process P in $L\pi$ there exists a process P' in $L\pi$ such that $P \approx P'$. Similarly, given a context $C[\cdot]$ in $L\pi$ there exists a context $\hat{C}[\cdot]$ in $L\pi$ such that $C[\llbracket P \rrbracket] \approx \hat{C}[\llbracket P \rrbracket] \dot{\approx} \hat{C}[\llbracket Q \rrbracket] \approx C[\llbracket Q \rrbracket]$. Since $\approx \dot{\approx} \approx \subseteq \dot{\approx}$ we can conclude. □

9.7 Operational soundness of CPS axioms

In his PhD thesis, Thielecke studies the target calculi of Continuation Passing Style transforms [57]. He introduces a CPS-calculus similar to the intermediate language of Appel's compiler [4]. The CPS-calculus is very simple and low-level: only variables may be passed as arguments, moreover application is like a jump, with variables as argument. The terms of the (recursive) CPS-calculus are given by the following grammar:

$$M ::= a\langle b \rangle \mid M\{a\langle b \rangle \Leftarrow M\}$$

The intended meaning is that $a\langle b \rangle$ is a jump to the continuation a with actual parameter b , while $M\{a\langle b \rangle \Leftarrow N\}$ binds the continuation with body N and formal parameter b to a in M . The calculus is recursive because in $M\{a\langle b \rangle \Leftarrow N\}$ the term N may refer to itself under a . For simplicity we consider a monadic variant of the CPS-calculus. The results of this sections can be straightforwardly extended to the polyadic CPS-calculus.

The set of free variables $\text{fv}(M)$ of a CPS term M is defined as follows.

- $\text{fv}(a\langle b \rangle) \stackrel{\text{def}}{=} \{a, b\}$
- $\text{fv}(M\{a\langle b \rangle \Leftarrow N\}) \stackrel{\text{def}}{=} (\text{fv}(M) \setminus \{a\}) \cup (\text{fv}(N) \setminus \{b\})$

The *axiomatic semantics* for the CPS-calculus is defined as the congruence induced by the following four axioms:

- (DISTR) $L\{a\langle b \rangle \Leftarrow M\}\{c\langle d \rangle \Leftarrow N\} = L\{c\langle d \rangle \Leftarrow N\}\{a\langle b \rangle \Leftarrow M\{c\langle d \rangle \Leftarrow N\}\}$
such that $a \neq c$ and $a, b \notin \text{fv}(N)$
- (GC) $a\langle b \rangle\{c\langle d \rangle \Leftarrow N\} = a\langle b \rangle, c \notin \text{fv}(a\langle b \rangle)$
- (JMP) $a\langle b \rangle\{a\langle c \rangle \Leftarrow N\} = N\{b/c\}\{a\langle c \rangle \Leftarrow N\}$
- (ETA) $M\{a\langle b \rangle \Leftarrow c\langle b \rangle\} = M\{c/a\}, a \neq c.$

The (JMP) law is in some sense what drives the computation. By contrast, (GC) and (DISTR) are “structural” laws similar to those of the π -calculus. Most of the axioms above appear in [4]. We write $\text{CPS} \vdash M = N$ to denote that the equality $M = N$ can be derived by the above axiomatic semantics.

Remark 9.15 *The CPS term $M_1\{a\langle b \rangle \Leftarrow M_2\}$ reminds us the construct $\text{def } a\langle x \rangle = M_2 \text{ in } M_1$ of the Join calculus. Actually, the CPS-calculus can be seen as a confluent subset of the Join calculus.*

In the remainder of this section we prove that the axiomatic semantics defined above is sound with respect to the operational semantics. To our knowledge this is the first proof of this result. Our proof relies on the theory of $L\pi$.

We give an operational semantics for the CPS-calculus (which is a slight variant of the operational semantics given by Thielecke). It is easy to see that every CPS-term M is in the form $a\langle b \rangle\{a_1\langle b_1 \rangle \Leftarrow M_1\} \dots \{a_n\langle b_n \rangle \Leftarrow M_n\}$ for some $n \geq 0$. This allows us to model the behaviour of CPS-terms by means of just one (global) reduction rule:

$$\begin{aligned} & a_i\langle b \rangle\{a_1\langle b_1 \rangle \Leftarrow M_1\} \dots \{a_i\langle b_i \rangle \Leftarrow M_i\} \dots \{a_n\langle b_n \rangle \Leftarrow M_n\} \\ & \quad \quad \quad \rightsquigarrow \\ & M_i\{b/b_i\}\{a_1\langle b_1 \rangle \Leftarrow M_1\} \dots \{a_i\langle b_i \rangle \Leftarrow M_i\} \dots \{a_n\langle b_n \rangle \Leftarrow M_n\} \end{aligned}$$

where $1 \leq i \leq n$ and $a_j \notin \text{fv}(M_i)$ for $1 \leq j < i$. The rule above is a “contextual” variant of the (JMP) axiom.

In the CPS-calculus the notion of observability is represented by the “external” jump that a term may perform after some internal jumps. For instance, in a jump of the form $a\langle b \rangle$, we can observe (the occurrence of a jump to) a . More generally, a free variable in the leftmost position can be observed.

Definition 9.16 (Observability in CPS-calculus) *Let M be a term of the CPS-calculus and a a name, we write $M \Downarrow_a$ if there are names $b, a_1, b_1, \dots, a_n, b_n$, for some integer $n \geq 0$ with $a \neq a_i$ for every $1 \leq i \leq n$, such that $M = a\langle b \rangle\{a_1\langle b_1 \rangle \Leftarrow M_1\} \dots \{a_n\langle b_n \rangle \Leftarrow M_n\}$. We write $M \Downarrow_a$ if there exists a CPS-term N such that $M \rightsquigarrow^* N \Downarrow_a$, where \rightsquigarrow^* denotes the reflexive and transitive closure of \rightsquigarrow .*

We denote with \cong_{CPS} the barbed congruence on CPS terms. We prove the soundness of the axiomatic semantics with respect to \cong_{CPS} by exploiting a straightforward encoding of the CPS-calculus into π -calculus already appeared in [57].

- $(a\langle b \rangle) \stackrel{\text{def}}{=} \bar{a}b$
- $(M\{a\langle b \rangle \Leftarrow N\}) \stackrel{\text{def}}{=} (\nu a)((M) \mid !a(b). (N)).$

There is a straightforward operational correspondence between a CPS-term M and its encoding (M) .

Lemma 9.17 (Operational correspondence of (\cdot)) *Let M be a CPS-term. Then:*

1. *If $M \rightsquigarrow N$ then $(M) \xrightarrow{\tau} \equiv (N)$.*
2. *If $(M) \xrightarrow{\tau} P$ then there is a CPS-term N such that $M \rightsquigarrow N$ and $P \equiv (N)$.*
3. *$M \Downarrow_a$ iff $(M) \Downarrow_a$.*

4. If $M \rightsquigarrow^* N$ then $\langle M \rangle \Longrightarrow \equiv \langle N \rangle$.
5. If $\langle M \rangle \Longrightarrow P$ then there is a CPS-term N s.t. $M \rightsquigarrow^* N$ and $P \equiv \langle N \rangle$.
6. $M \Downarrow_a$ iff $\langle M \rangle \Downarrow_a$.

Proof: The proofs of parts 1, 2, and 3 are easy. Parts 4 and 5 are proved by induction on the number of silent moves. Part 6 is a consequence of previous parts. \square

Lemma 9.18 *Let M and N be two CPS-terms. Then:*

$$\langle M \rangle \cong_{L\pi} \langle N \rangle \text{ implies } M \cong_{\text{CPS}} N.$$

Proof: It follows from the operational correspondence in Lemma 9.17 and the compositionality of $\langle \cdot \rangle$. \square

Lemma 9.19 *Let M and N be two CPS-terms. Then:*

$$\text{CPS} \vdash M=N \text{ implies } \langle M \rangle \cong_{L\pi} \langle N \rangle.$$

Proof: Since $\cong_{L\pi}$ is a congruence, it suffices to prove the soundness of the four axioms (DISTR), (GC), (JMP), and (ETA). More precisely, we prove that if $M = N$ is obtained by applying one of these axioms then $\langle M \rangle \cong_{L\pi} \langle N \rangle$. Let us consider the four possible cases.

1. (DISTR). By applying the encoding $\langle \cdot \rangle$ to the distributive law we get an instance of the replication theorems seen in Section 9.2. So, we prove this case by simply exploiting Theorem 9.4 and Milner's replication theorem for restriction and input prefix [31].
2. (GC). It suffices to show that

$$(\nu c)(!c(d). \langle N \rangle \mid \bar{a}b) \approx \bar{a}b$$

by exhibiting the appropriate bisimulation. Since \approx implies $\cong_{L\pi}$ we can conclude.

3. (JMP). It suffices to show that

$$(\nu a)(\bar{a}b \mid !a(c).P) \approx (\nu a)(P\{b/c\} \mid !a(c).P)$$

by proving that the relation

$$\mathcal{S} = \{ ((\nu a)(\bar{a}b \mid !a(c).P), (\nu a)(P\{b/c\} \mid !a(c).P)) \} \cup \approx$$

is a synchronous ground bisimulation up to \equiv . Since \approx implies $\cong_{L\pi}$ we can conclude.

4. (ETA). This is an application of Proposition 9.1.

\square

Note that in the previous proof, laws (DISTR) and (ETA) cannot be proved in π or π_a .

Theorem 9.20 (Soundness of the axiomatic semantics) *Let M and N be two CPS-terms. Then:*

$$\text{CPS} \vdash M=N \text{ implies } M \cong_{\text{CPS}} N.$$

Proof: By Lemmas 9.18 and 9.19. \square

We do not know whether the above axiomatic semantics is complete.

A Proofs

A.1 Proofs of Lemmas 5.10 and 5.12

For the sake of clarity we restate the result as follows.

Lemma A.1 *Let P and Q be two $\mathcal{L}\pi$ -processes such that $P \simeq_a Q$. Then:*

1. $(\nu a)P \simeq_a (\nu a)Q$
2. $P \mid R \simeq_a Q \mid R$, for all $\mathcal{L}\pi$ -process R
3. $a(x).P \simeq_a a(x).Q$
4. $!a(x).P \simeq_a !a(x).Q$.

Proof: 1. It suffices to show that the relation

$$\mathcal{S} = \{((\nu a)P, (\nu a)Q) : P, Q \in \mathcal{L}\pi \text{ and } P \simeq_a Q\}$$

is a \simeq_a -bisimulation up-to structural congruence. The proof is easy because the output actions performed by an $\mathcal{L}\pi$ -process are always bound. We work up to structural congruence when dealing with the asynchronous clause for input.

2. We prove that the relation

$$\mathcal{S} = \{((\nu \tilde{a})(P \mid R), (\nu \tilde{a})(Q \mid R)) : P, Q, R \in \mathcal{L}\pi \text{ and } P \simeq_a Q\}$$

is a \simeq_a -bisimulation up to \succeq and \approx . Let us consider the possible actions of $(\nu \tilde{a})(P \mid R)$:

- (a) If $(\nu \tilde{a})(P \mid R) \xrightarrow{\bar{b}(c)} A$, with c fresh and $b \notin \tilde{a}$, then there are two cases:
 - i. either $R \xrightarrow{\bar{b}(c)} R'$, for some R' , and $A = (\nu \tilde{a})(P \mid R')$. Process $(\nu \tilde{a})(Q \mid R)$ can match this action in the same way;
 - ii. or $P \xrightarrow{\bar{b}(c)} P'$ for some P' . This means $A = (\nu \tilde{a})(P' \mid R)$. Since $P \simeq_a Q$ there exist Q' such that $Q \xrightarrow{\bar{b}(c)} Q'$ and $P' \simeq_a Q'$. So, $(\nu \tilde{a})(Q \mid R) \xrightarrow{\bar{b}(c)} (\nu \tilde{a})(Q' \mid R)$ and $((\nu \tilde{a})(P' \mid R), (\nu \tilde{a})(Q' \mid R)) \in \mathcal{S}$.
- (b) If $(\nu \tilde{a})(P \mid R) \xrightarrow{b(c)} A$, with c fresh and $b \notin \tilde{a}$, then there are two cases:
 - i. either $R \xrightarrow{b(c)} R'$, for some R' , and then we can proceed as in case (1a);
 - ii. or $P \xrightarrow{b(c)} P'$ and $A = (\nu \tilde{a})(P' \mid R)$. Since $P \simeq_a Q$, there are two possible cases:
 - A. either $Q \xrightarrow{b(c)} Q'$, with $P' \simeq_a Q'$, and we can easily conclude;
 - B. or $Q \Longrightarrow Q'$, with $P' \simeq_a Q' \mid \llbracket \bar{b}c \rrbracket$. This means that $(\nu \tilde{a})(Q \mid R) \Longrightarrow (\nu \tilde{a})(Q' \mid R)$ with $(\nu \tilde{a})(P' \mid R) \mathcal{S} (\nu \tilde{a})(Q' \mid \llbracket \bar{b}c \rrbracket \mid R) \equiv (\nu \tilde{a})(Q' \mid R) \mid \llbracket \bar{b}c \rrbracket$, which is enough because \equiv is contained in \approx and \mathcal{S} is a \simeq_a -bisimulation up to \succeq and \approx .
- (c) If $(\nu \tilde{a})(P \mid R) \xrightarrow{\tau} A$, there are four cases:
 - i. $P \xrightarrow{\tau} P'$. This case is easy.
 - ii. $R \xrightarrow{\tau} R'$. This case is easy.
 - iii. $P \xrightarrow{\bar{b}(c)} P', R \xrightarrow{b(c)} R'$ and $(\nu \tilde{a})(P \mid R) \xrightarrow{\tau} (\nu \tilde{a}c)(P' \mid R')$. Since $P \simeq_a Q$ there exists Q' such that $Q \xrightarrow{\bar{b}(c)} Q'$ and $P' \simeq_a Q'$. This means that $(\nu \tilde{a})(Q \mid R) \Longrightarrow (\nu \tilde{a}c)(Q' \mid R')$ and $((\nu \tilde{a}c)(P' \mid R'), (\nu \tilde{a}c)(Q' \mid R')) \in \mathcal{S}$.

iv. $P \xrightarrow{b(c)} P', R \xrightarrow{\bar{b}(c)} R'$ and $(\nu \tilde{a})(P \mid R) \xrightarrow{\tau} (\nu \tilde{a}c)(P' \mid R')$. Since $P \approx_a Q$ there are two cases:

- A. either there exists Q' such that $Q \xrightarrow{b(c)} Q'$ with $P' \approx_a Q'$, and then we can conclude;
- B. or there exists Q' such that $Q \Longrightarrow Q'$ and $P' \approx_a Q' \mid \llbracket \bar{b}c \rrbracket$. In this case, by Lemma 5.9(2), $R \approx (\nu c)(\llbracket \bar{b}c \rrbracket \mid R')$ and therefore

$$(\nu \tilde{a})(Q \mid R) \Longrightarrow (\nu \tilde{a})(Q' \mid R)$$

with

$$(\nu \tilde{a}c)(P' \mid R') \mathcal{S} (\nu \tilde{a}c)(Q' \mid \llbracket \bar{b}c \rrbracket \mid R') \approx (\nu \tilde{a})(Q' \mid R).$$

3. It suffices to show that the relation

$$S = \{(a(x).P, a(x).Q) : P, Q \in \mathcal{L}\pi \text{ and } P \approx_a Q\}$$

is a \approx_a -bisimulation. The proof relies on the fact that \approx_a is preserved by injective substitutions: since \approx_a is ground, in the input clause only fresh names are received.

4. We prove that the relation \mathcal{S} defined below

$$\{(P_1 \mid !a(x).Q_1, P_2 \mid !a(x).Q_2) : P_1, P_2, Q_1, Q_2 \in \mathcal{L}\pi, P_1 \approx_a P_2, Q_1 \approx_a Q_2\}$$

is a \approx_a -bisimulation up to structural congruence (it is a special case of the proof technique of Definition 5.7). If $P_1 \mid !a(x).Q_1 \xrightarrow{\mu} R$ for some action μ and some process R then there are three possible cases:

- (a) $P_1 \xrightarrow{\mu} P'_1$ and $R = P'_1 \mid !a(x).Q_1$. Then, since $P_1 \approx_a P_2$, we can easily conclude.
- (b) $\mu = a(w)$ and $P_1 \mid !a(x).Q_1 \xrightarrow{a(w)} P_1 \mid Q_1\{w/x\} \mid !a(x).Q_1$. On the other side we have $P_2 \mid !a(x).Q_2 \xrightarrow{a(w)} P_2 \mid Q_2\{w/x\} \mid !a(x).Q_2$. Since $Q_1 \approx_a Q_2$, and \approx_a is preserved by injective substitutions, we have $Q_1\{w/x\} \approx_a Q_2\{w/x\}$. By Lemma 5.10(2) we have $P_1 \mid Q_1\{w/x\} \approx_a P_2 \mid Q_1\{w/x\} \approx_a P_2 \mid Q_2\{w/x\}$. By transitivity (Lemma 5.11(3)) we conclude that $P_1 \mid Q_1\{w/x\} \mid !a(x).Q_1 \mathcal{S} P_2 \mid Q_2\{w/x\} \mid !a(x).Q_2$.
- (c) $P_1 \xrightarrow{\bar{a}(c)} P'_1$ and $P_1 \mid !a(x).Q_1 \xrightarrow{\tau} (\nu c)(P'_1 \mid Q_1\{c/x\}) \mid !a(x).Q_1$. Since $P_1 \approx_a P_2$, there exists P'_2 such that $P_2 \xrightarrow{\bar{a}(c)} P'_2$ and $P'_1 \approx_a P'_2$. This means that $P_2 \mid !a(x).Q_2 \Longrightarrow (\nu c)(P'_2 \mid Q_2\{c/x\}) \mid !a(x).Q_2$. We reason as in the previous case, and by applying Lemmas 5.10(2), 5.11(3), and 5.10(1) we conclude.

□

A.2 Proof of Lemma 6.3

We already pointed out in Lemma 5.1 that there exists an operational correspondence on strong transitions between processes P and $\llbracket P \rrbracket$. Boreale also proved a weak operational correspondence between processes P and $\llbracket P \rrbracket$.

Lemma A.2 (Boreale [7]) *Let P be an $\mathcal{L}\pi$ -process.*

1. *Suppose that $P \xrightarrow{\alpha} P'$. Then we have:*

- (a) *if $\alpha = a(b)$ then $\llbracket P \rrbracket \xrightarrow{a(b)} \gtrsim \llbracket P' \rrbracket$;*
- (b) *if $\alpha = \bar{a}b$ then $\llbracket P \rrbracket \xrightarrow{\bar{a}(p)} \gtrsim (p \rightarrow b \mid \llbracket P' \rrbracket)$, with $p \notin \text{fn}(P')$;*
- (c) *if $\alpha = \bar{a}(b)$ then $\llbracket P \rrbracket \xrightarrow{\bar{a}(p)} \gtrsim (\nu b)(p \rightarrow b \mid \llbracket P' \rrbracket)$, with $p \notin \text{fn}(P')$;*

(d) if $\alpha = \tau$ then $\llbracket P \rrbracket \xrightarrow{\tau} \gtrsim \llbracket P' \rrbracket$.

2. Suppose that $\llbracket P \rrbracket \xrightarrow{\alpha} P_1$. Then there exists $P' \in \text{L}\pi$ such that:

(a) if $\alpha = a(b)$ then $P \xrightarrow{a(b)} P'$, with $P_1 \gtrsim \llbracket P' \rrbracket$;

(b) if $\alpha = \bar{a}(p)$ then:

i. either $P \xrightarrow{\bar{a}b} P'$, with $p \notin \text{fn}(P')$ and $P_1 \gtrsim (p \rightarrow b \mid \llbracket P' \rrbracket)$,

ii. or $P \xrightarrow{\bar{a}(b)} P'$, with $p \notin \text{fn}(P')$ and $P_1 \gtrsim (\nu b)(p \rightarrow b \mid \llbracket P' \rrbracket)$;

(c) if $\alpha = \tau$ then $P \xrightarrow{\tau} P'$ with $P_1 \gtrsim \llbracket P' \rrbracket$.

This result will be used to prove Lemma 6.3 which we restate here.

Lemma A.3 *Let P and Q be two processes in $\text{L}\pi$. Then:*

$$P \approx_1 Q \text{ iff } \llbracket P \rrbracket \simeq_a \llbracket Q \rrbracket.$$

Proof: We prove the implication *from left to right*.

We show that the relation

$$\mathcal{S} = \{(\llbracket P \rrbracket, \llbracket Q \rrbracket) \mid P, Q \in \text{L}\pi \text{ and } P \approx_1 Q\}$$

is a \simeq_a -bisimulation up-to \gtrsim . Let us consider the three possible actions for $\llbracket P \rrbracket$:

1. If $\llbracket P \rrbracket \xrightarrow{\tau} P_1$, by lemma 5.1, there exists P' such that $P \xrightarrow{\tau} P'$ and $P_1 \gtrsim \llbracket P' \rrbracket$. Since $P \approx_1 Q$, there exists Q' such that $Q \Longrightarrow Q'$ and also $P' \approx_1 Q'$. By Lemma A.2, there exists Q_1 such that $\llbracket Q \rrbracket \xrightarrow{\tau} Q_1 \gtrsim \llbracket Q' \rrbracket$.

2. If $\llbracket P \rrbracket \xrightarrow{a(c)} P_1$, by Lemma 5.1, there exists P' such that $P \xrightarrow{a(c)} P'$ and $P_1 \gtrsim \llbracket P' \rrbracket$. Since $P \approx_1 Q$ there are two possibilities:

(a) There exists Q' such that $Q \xrightarrow{a(c)} Q'$ and $P' \approx_1 Q'$. Then, by Lemma A.2, there exists Q_1 such that $\llbracket Q \rrbracket \xrightarrow{a(c)} Q_1 \gtrsim \llbracket Q' \rrbracket$.

(b) There exists Q' such that $Q \Longrightarrow Q'$ and $P' \approx_1 Q' \mid \bar{a}c$. Then, by Lemma A.2, there exists Q_1 such that $\llbracket Q \rrbracket \Longrightarrow Q_1 \gtrsim \llbracket Q' \rrbracket$. Notice that $Q_1 \gtrsim \llbracket Q' \rrbracket$ implies $Q_1 \mid \llbracket \bar{a}c \rrbracket \gtrsim \llbracket Q' \mid \bar{a}c \rrbracket$.

3. If $\llbracket P \rrbracket \xrightarrow{\bar{a}(p)} P_1$, assuming p fresh, by Lemma 5.1, there are two possible cases:

(a) $P \xrightarrow{\bar{a}b} P'$ and $P_1 \gtrsim (p \rightarrow b \mid \llbracket P' \rrbracket) = \llbracket p \triangleright b \mid P' \rrbracket$. Since $P \approx_1 Q$, there are still two cases:

i. There exists a process Q' such that $Q \xrightarrow{\bar{a}d} Q'$ and $(p \triangleright b \mid P') \approx_1 (p \triangleright d \mid Q')$. By Lemma A.2 there exists Q_1 such that $\llbracket Q \rrbracket \xrightarrow{\bar{a}(p)} Q_1 \gtrsim (p \rightarrow d \mid \llbracket Q' \rrbracket) = \llbracket p \triangleright d \mid Q' \rrbracket$. So, $\llbracket P \rrbracket \xrightarrow{\bar{a}(p)} P_1 \gtrsim \llbracket p \triangleright b \mid P' \rrbracket$, and $\llbracket Q \rrbracket \xrightarrow{\bar{a}(p)} Q_1 \gtrsim \llbracket p \triangleright d \mid Q' \rrbracket$, and we can conclude since $(\llbracket p \triangleright b \mid P' \rrbracket, \llbracket p \triangleright d \mid Q' \rrbracket) \in \mathcal{S}$.

ii. There exists a process Q' such that $Q \xrightarrow{\bar{a}(c)} Q'$ and $(p \triangleright b \mid P') \approx_1 (\nu c)(p \triangleright c \mid Q')$. By Lemma A.2 there exists Q_1 such that $\llbracket Q \rrbracket \xrightarrow{\bar{a}(p)} Q_1 \gtrsim (\nu c)(p \rightarrow c \mid \llbracket Q' \rrbracket)$. So, $\llbracket P \rrbracket \xrightarrow{\bar{a}(p)} P_1 \gtrsim \llbracket p \triangleright b \mid P' \rrbracket$ and $\llbracket Q \rrbracket \xrightarrow{\bar{a}(p)} Q_1 \gtrsim \llbracket (\nu c)(p \triangleright c \mid Q') \rrbracket$, and we can conclude since $(\llbracket p \triangleright b \mid P' \rrbracket, \llbracket (\nu c)(p \triangleright c \mid Q') \rrbracket) \in \mathcal{S}$.

(b) $P \xrightarrow{\bar{a}(c)} P'$ and $P_1 \gtrsim (\nu c)(p \rightarrow c \mid \llbracket P' \rrbracket) = \llbracket (\nu c)(p \triangleright c \mid P') \rrbracket$. Since $P \approx_1 Q$, there are two possibilities:

- i. There exists Q' such that $Q \xrightarrow{\bar{a}b} Q'$ and $(\nu c)(p \triangleright c \mid P') \approx_1 (p \triangleright b \mid Q')$. By Lemma A.2, there exists a process Q_1 such that $\llbracket Q \rrbracket \xrightarrow{\bar{a}(p)} Q_1 \gtrsim (p \rightarrow b \mid Q')$. So, $\llbracket P \rrbracket \xrightarrow{\bar{a}(p)} P_1 \gtrsim \llbracket (\nu c)(p \triangleright c \mid P') \rrbracket$ and $\llbracket Q \rrbracket \xrightarrow{\bar{a}(p)} Q_1 \gtrsim \llbracket p \triangleright b \mid Q' \rrbracket$, and we can conclude since $(\llbracket (\nu c)(p \triangleright c \mid P') \rrbracket, \llbracket p \triangleright b \mid Q' \rrbracket) \in \mathcal{S}$.
- ii. There exists Q' such that $Q \xrightarrow{\bar{a}(c)} Q'$ and $(\nu c)(p \triangleright c \mid P') \approx_1 (\nu c)(p \triangleright c \mid Q')$. By Lemma A.2, there exists a process Q_1 such that $\llbracket Q \rrbracket \xrightarrow{\bar{a}(p)} Q_1 \gtrsim (\nu c)(p \rightarrow c \mid \llbracket Q' \rrbracket)$. So, $\llbracket P \rrbracket \xrightarrow{\bar{a}(p)} P_1 \gtrsim \llbracket (\nu c)(p \triangleright c \mid P') \rrbracket$ and $\llbracket Q \rrbracket \xrightarrow{\bar{a}(p)} Q_1 \gtrsim \llbracket (\nu c)(p \triangleright c \mid Q') \rrbracket$, and we can conclude since $(\llbracket (\nu c)(p \triangleright c \mid P') \rrbracket, \llbracket (\nu c)(p \triangleright c \mid Q') \rrbracket) \in \mathcal{S}$.

We prove the implication *from right to left*. We show that the relation

$$\mathcal{S} = \{(P, Q) \mid P, Q \in \text{L}\pi \text{ and } \llbracket P \rrbracket \asymp_a \llbracket Q \rrbracket\}$$

is a link bisimulation. Let us consider the four possible actions.

1. If $P \xrightarrow{\tau} P'$, by Lemma 5.1, there exists P_1 such that $\llbracket P \rrbracket \xrightarrow{\tau} P_1 \gtrsim \llbracket P' \rrbracket$. Since $\llbracket P \rrbracket \asymp_a \llbracket Q \rrbracket$, there exists Q_1 such that $\llbracket Q \rrbracket \xrightarrow{\tau} Q_1$ and $P_1 \asymp_a Q_1$. By Lemma A.2, there exists a process Q' such that $Q \xrightarrow{\tau} Q'$ and $Q_1 \gtrsim \llbracket Q' \rrbracket$. So, we have $\llbracket P' \rrbracket \lesssim P_1 \asymp_a Q_1 \gtrsim \llbracket Q' \rrbracket$. Since \lesssim and \gtrsim are included in \asymp_a , and \asymp_a is transitive, we conclude that $(P', Q') \in \mathcal{S}$.
2. If $P \xrightarrow{a(c)} P'$, by Lemma 5.1, there exists P_1 such that $\llbracket P \rrbracket \xrightarrow{a(c)} P_1 \gtrsim \llbracket P' \rrbracket$. Since $\llbracket P \rrbracket \asymp_a \llbracket Q \rrbracket$ we have two cases:
 - (a) There exists a processes Q_1 such that $\llbracket Q \rrbracket \xrightarrow{a(c)} Q_1$ and $P_1 \asymp_a Q_1$. By Lemma A.2 there exists a process Q' such that $Q \xrightarrow{a(c)} Q'$ and $Q_1 \gtrsim \llbracket Q' \rrbracket$. So, we have $\llbracket P' \rrbracket \lesssim P_1 \asymp_a Q_1 \gtrsim \llbracket Q' \rrbracket$. We can therefore conclude that $(P', Q') \in \mathcal{S}$.
 - (b) There exists Q_1 such that $\llbracket Q \rrbracket \Longrightarrow Q_1$ and $P_1 \asymp_a Q_1 \mid \llbracket \bar{a}c \rrbracket$. By Lemma A.2 there exists a process Q' such that $Q \Longrightarrow Q'$ and $Q_1 \gtrsim \llbracket Q' \rrbracket$. Notice that $Q_1 \mid \llbracket \bar{a}c \rrbracket \gtrsim \llbracket Q' \mid \bar{a}c \rrbracket$. So, we have

$$\llbracket P' \rrbracket \lesssim P_1 \asymp_a Q_1 \mid \llbracket \bar{a}c \rrbracket \gtrsim \llbracket Q' \mid \bar{a}c \rrbracket.$$

We can therefore conclude that $(P', Q' \mid \bar{a}c) \in \mathcal{S}$.

3. If $P \xrightarrow{\bar{a}b} P'$, by Lemma 5.1, there exists P_1 such that $\llbracket P \rrbracket \xrightarrow{\bar{a}(p)} P_1 \gtrsim p \rightarrow b \mid \llbracket P' \rrbracket = \llbracket p \triangleright b \mid P' \rrbracket$. Since $\llbracket P \rrbracket \asymp_a \llbracket Q \rrbracket$ there exists Q_1 such that $\llbracket Q \rrbracket \xrightarrow{\bar{a}(p)} Q_1$ and $P_1 \asymp_a Q_1$. By Lemma A.2, we have two possibilities:
 - (a) There exists Q' such that $Q \xrightarrow{\bar{a}d} Q'$ and $Q_1 \gtrsim p \rightarrow d \mid \llbracket Q' \rrbracket = \llbracket p \triangleright d \mid Q' \rrbracket$. So, we have $\llbracket p \triangleright b \mid P' \rrbracket \lesssim P_1 \asymp_a Q_1 \gtrsim \llbracket p \triangleright d \mid Q' \rrbracket$. We can therefore conclude that $((p \triangleright b \mid P'), (p \triangleright d \mid Q')) \in \mathcal{S}$.
 - (b) There exists Q' such that $Q \xrightarrow{\bar{a}(c)} Q'$ and $Q_1 \gtrsim (\nu c)(p \rightarrow c \mid \llbracket Q' \rrbracket) = \llbracket (\nu c)(p \rightarrow c \mid Q') \rrbracket$. So, we have $\llbracket p \triangleright b \mid P' \rrbracket \lesssim P_1 \asymp_a Q_1 \gtrsim \llbracket (\nu c)(p \triangleright c \mid Q') \rrbracket$. We can therefore conclude that $((p \triangleright b \mid P'), (\nu c)(p \triangleright c \mid Q')) \in \mathcal{S}$.
4. $P \xrightarrow{\bar{a}(c)} P'$, by Lemma 5.1 there exists P_1 such that $\llbracket P \rrbracket \xrightarrow{\bar{a}(p)} P_1 \gtrsim (\nu c)(p \rightarrow c \mid \llbracket P' \rrbracket) = \llbracket (\nu c)(p \triangleright c \mid P') \rrbracket$. Since $\llbracket P \rrbracket \asymp_a \llbracket Q \rrbracket$ there exists Q_1 such that $\llbracket Q \rrbracket \xrightarrow{\bar{a}(p)} Q_1$ and $P_1 \asymp_a Q_1$. By Lemma A.2 we have two possibilities:
 - (a) There exists Q' such that $Q \xrightarrow{\bar{a}b} Q'$ and $Q_1 \gtrsim p \rightarrow b \mid \llbracket Q' \rrbracket = \llbracket p \triangleright b \mid Q' \rrbracket$. So, we have $\llbracket (\nu c)(p \triangleright c \mid P') \rrbracket \lesssim P_1 \asymp_a Q_1 \gtrsim \llbracket p \triangleright b \mid Q' \rrbracket$. We can therefore conclude that $((\nu c)(p \triangleright c \mid P'), (p \triangleright b \mid Q')) \in \mathcal{S}$.

- (b) There exists Q' such that $Q \xrightarrow{\bar{a}(c)} Q'$ and $Q_1 \succ (\nu c)(p \rightarrow c \mid \llbracket Q' \rrbracket)$. So, we have $\llbracket (\nu c)(p \triangleright c \mid P') \rrbracket \lesssim P_1 \approx_a Q_1 \succ \llbracket (\nu c)(p \triangleright c \mid Q') \rrbracket$. We can therefore conclude that $((\nu c)(p \triangleright c \mid P'), ((\nu c)(p \triangleright c \mid Q'))) \in \mathcal{S}$.

□

A.3 Complement to the Proof of Lemma 7.1

Proof: The proof is by induction on n . The case $n = 0$ is trivial because $\simeq_1^0 = L\pi \times L\pi$. If $n > 0$, by induction, we suppose that

$$(\nu \mathcal{L}')(P \mid R(n, L)) \dot{\simeq} (\nu \mathcal{L}')(Q \mid R(n, L)) \text{ and } P \xrightarrow{\mu} P'.$$

We proceed by case analysis on the action μ to show that Q can match the action μ .

1. $\mu = \tau$. Then:

$$(\nu \mathcal{L}')(P \mid R(n, \mathcal{L}, \mathcal{M})) \xrightarrow{\tau} (\nu \mathcal{L}')(P \mid (\bar{c}_n^r \oplus R(n-1, \mathcal{L}, \mathcal{M})))$$

To match this reduction up to barbed bisimulation we have to have:

$$(\nu \mathcal{L}')(Q \mid R(n, \mathcal{L}, \mathcal{M})) \xrightarrow{\tau} (\nu \mathcal{L}')(Q_1 \mid (\bar{c}_n^r \oplus R(n-1, \mathcal{L}, \mathcal{M})))$$

We make a further reduction on the left handside

$$(\nu \mathcal{L}')(P \mid (\bar{c}_n^r \oplus R(n-1, \mathcal{L}, \mathcal{M}))) \xrightarrow{\tau} (\nu \mathcal{L}')(P' \mid R(n-1, \mathcal{L}, \mathcal{M}))$$

Again this has to be matched by (note that we cannot run the process $R(n-1, \mathcal{L}, \mathcal{M})$ without losing a commitment \bar{b}_n or \bar{b}'_n):

$$(\nu \mathcal{L}')(Q_1 \mid (\bar{c}_n^r \oplus R(n-1, \mathcal{L}, \mathcal{M}))) \xrightarrow{\tau} (\nu \mathcal{L}')(Q' \mid R(n-1, \mathcal{L}, \mathcal{M}))$$

We observe that $Q \xrightarrow{\tau} Q_1 \xrightarrow{\tau} Q'$ and we conclude by applying the inductive hypothesis.

2. $\mu = \bar{a}b$. We may suppose $b \in L$. Then

$$\begin{aligned} & (\nu \mathcal{L}')(Q \mid R(n, \mathcal{L}, \mathcal{M})) \xrightarrow{\tau} \\ & (\nu \mathcal{L}')(Q_1 \mid \bar{c}_n^a \oplus a(x). (a' \triangleright x \mid R(n-1, \mathcal{L} \cup \{a'\}, \mathcal{M} \cup \{a'\}))) \end{aligned}$$

We take a further step on the lhs:

$$\begin{aligned} & (\nu \mathcal{L}')(P \mid \bar{c}_n^a \oplus a(x). (a' \triangleright x \mid R(n-1, \mathcal{L} \cup \{a'\}, \mathcal{M} \cup \{a'\}))) \xrightarrow{\tau} \\ & (\nu \mathcal{L}')(P' \mid a' \triangleright b \mid R(n-1, \mathcal{L} \cup \{a'\}, \mathcal{M} \cup \{a'\})) \end{aligned}$$

We take a further step on the lhs:

$$\begin{aligned} & (\nu \mathcal{L}')(P \mid \bar{c}_n^a \oplus a(x). (a' \triangleright x \mid R(n-1, \mathcal{L} \cup \{a'\}, \mathcal{M} \cup \{a'\}))) \xrightarrow{\tau} \\ & (\nu \mathcal{L}')(P' \mid a' \triangleright b \mid R(n-1, \mathcal{L} \cup \{a'\}, \mathcal{M} \cup \{a'\})) \end{aligned}$$

This can be matched:

- (a) either by

$$\begin{aligned} & (\nu \mathcal{L}')(Q_1 \mid \bar{c}_n^a \oplus a(x). (a' \triangleright x \mid R(n-1, \mathcal{L} \cup \{a'\}, \mathcal{M} \cup \{a'\}))) \xrightarrow{\tau} \\ & (\nu \mathcal{L}')(Q' \mid a' \triangleright d \mid R(n-1, \mathcal{L} \cup \{a'\}, \mathcal{M} \cup \{a'\})) \end{aligned}$$

This means that $Q \xrightarrow{\tau} Q_1 \xrightarrow{\bar{a}d} Q'$. By inductive hypothesis, and reasoning up to structural congruence, we can conclude that $a' \triangleright b \mid P' \simeq_1^{n-1} a' \triangleright d \mid Q'$.

(b) or by

$$\begin{aligned} (\nu\mathcal{L}')(Q_1 \mid \overline{c_n^a} \oplus a(x). (a' \triangleright x \mid R(n-1, \mathcal{L} \cup \{a'\}, \mathcal{M} \cup \{a'\}))) &\xrightarrow{\tau} \\ (\nu\mathcal{L}')((\nu c)(Q' \mid a' \triangleright c) \mid R(n-1, \mathcal{L} \cup \{a'\}, \mathcal{M} \cup \{a'\})) & \end{aligned}$$

This means that that $Q \xrightarrow{\tau} Q_1 \xrightarrow{\overline{a(c)}} Q'$. By inductive hypothesis, and reasoning up to structural congruence, we can conclude that $a' \triangleright b \mid P' \simeq_1^{n-1} (\nu c)(a' \triangleright c \mid Q')$.

3. $\mu = \overline{a(c)}$. We may suppose $c \notin \text{fn}(Q)$. Then

$$\begin{aligned} (\nu\mathcal{L}')(P \mid R(n, \mathcal{L}, \mathcal{M})) &\xrightarrow{\tau} \\ (\nu\mathcal{L}')(P \mid \overline{c_n^a} \oplus a(x). (a' \triangleright x \mid R(n-1, \mathcal{L} \cup \{a'\}, \mathcal{M} \cup \{a'\}))) & \end{aligned}$$

This has to be matched by:

$$\begin{aligned} (\nu\mathcal{L}')(Q \mid R(n, \mathcal{L}, \mathcal{M})) &\xrightarrow{\tau} \\ (\nu\mathcal{L}')(Q_1 \mid \overline{c_n^a} \oplus a(x). (a' \triangleright x \mid R(n-1, \mathcal{L} \cup \{a'\}, \mathcal{M} \cup \{a'\}))) & \end{aligned}$$

We take a further step on the lhs:

$$\begin{aligned} (\nu\mathcal{L}')(P \mid \overline{c_n^a} \oplus a(x). (a' \triangleright x \mid R(n-1, \mathcal{L} \cup \{a'\}, \mathcal{M} \cup \{a'\}))) &\xrightarrow{\tau} \\ (\nu\mathcal{L}')((\nu c)(P' \mid a' \triangleright c) \mid R(n-1, \mathcal{L} \cup \{a'\}, \mathcal{M} \cup \{a'\})) & \end{aligned}$$

This can be matched:

(a) either by

$$\begin{aligned} (\nu\mathcal{L}')(Q_1 \mid \overline{c_n^a} \oplus a(x). (a' \triangleright x \mid R(n-1, \mathcal{L} \cup \{a'\}, \mathcal{M} \cup \{a'\}))) &\xrightarrow{\tau} \\ (\nu\mathcal{L}')(Q' \mid a' \triangleright b \mid R(n-1, \mathcal{L} \cup \{a'\}, \mathcal{M} \cup \{a'\})) & \end{aligned}$$

This means that $Q \xrightarrow{\tau} Q_1 \xrightarrow{\overline{ab}} Q'$. By inductive hypothesis, and reasoning up to structural congruence, we can conclude that $(\nu c)(a' \triangleright c \mid P') \simeq_1^{n-1} a' \triangleright b \mid Q'$.

(b) or by

$$\begin{aligned} (\nu\mathcal{L}')(Q_1 \mid \overline{c_n^a} \oplus a(x). (a' \triangleright x \mid R(n-1, \mathcal{L} \cup \{a'\}, \mathcal{M} \cup \{a'\}))) &\xrightarrow{\tau} \\ (\nu\mathcal{L}')((\nu d)(Q' \mid a' \triangleright d) \mid R(n-1, \mathcal{L} \cup \{a'\}, \mathcal{M} \cup \{a'\})) & \end{aligned}$$

This means that $Q \xrightarrow{\tau} Q_1 \xrightarrow{\overline{a(d)}} Q'$. Since $c \notin \text{fn}(Q)$ we also have that $Q \xrightarrow{\tau} Q_1$ and $Q_1 \xrightarrow{\overline{a(c)}} Q'\{c/d\}$. By inductive hypothesis, and reasoning up to structural congruence, we can conclude that $(\nu c)(a' \triangleright c \mid P') \simeq_1^{n-1} (\nu c)(a' \triangleright c \mid Q')$.

4. $\mu = aa'$. We may suppose a' is the first element in $\text{Ch}'' \setminus \text{L}$ (otherwise we rename and use injective substitution). Then

$$(\nu\mathcal{L}')(P \mid R(n, \mathcal{L}, \mathcal{M})) \xrightarrow{\tau} (\nu\mathcal{L}')(P \mid (\overline{c_n^a} \oplus ((\nu a')(\overline{aa'} \mid R(n-1, \mathcal{L} \cup \{a', \mathcal{M}\}))))))$$

This has to be matched by

$$(\nu\mathcal{L}')(Q \mid R(n, \mathcal{L}, \mathcal{M})) \xrightarrow{\tau} (\nu\mathcal{L}')(Q_1 \mid (\overline{c_n^a} \oplus ((\nu a')(\overline{aa'} \mid R(n-1, \mathcal{L} \cup \{a', \mathcal{M}\}))))))$$

We make a further reduction on the lhs:

$$(\nu \mathcal{L}')(P \mid (\overline{c_n^a} \oplus ((\nu a')(\overline{a}a' \mid R(n-1, \mathcal{L} \cup \{a', \mathcal{M}\})))))) \xrightarrow{\tau} (\nu \mathcal{L}'a')(P' \mid R(n-1, \mathcal{L} \cup \{a', \mathcal{M}\}))$$

This is matched by:

$$(\nu \mathcal{L}')(Q_1 \mid (\overline{c_n^a} \oplus ((\nu a')(\overline{a}a' \mid R(n-1, \mathcal{L} \cup \{a', \mathcal{M}\})))))) \xrightarrow{\tau} Q''$$

We have two possibilities:

(a) $Q_1 \xrightarrow{\tau} Q'$ and $Q'' \equiv (\nu \mathcal{L}'a')(Q' \mid \overline{a}a' \mid R(n-1, \mathcal{L} \cup \{a', \mathcal{M}\}))$.

Then $Q \xrightarrow{\tau} Q_1 \xrightarrow{\tau} Q'$ and $P' \simeq_1^{n-1} Q' \mid \overline{a}a'$ by inductive hypothesis and up to structural congruence.

(b) $Q_1 \xrightarrow{aa'} Q'$ and $Q'' \equiv (\nu \mathcal{L}'a')(Q' \mid R(n-1, \mathcal{L} \cup \{a', \mathcal{M}\}))$. Then $Q \xrightarrow{\tau} Q_1 \xrightarrow{aa'} Q'$ and $P' \simeq_1^{n-1} Q'$ by inductive hypothesis and up to structural congruence.

□

A.4 Complement to the proof of Theorem 8.4

Lemma A.4 *Let P and Q be two $L\pi$ -processes and p a name such that $p \notin \text{fn}(P, Q)$. Then $(p \triangleright b \mid P) \approx_1 (p \triangleright b \mid Q)$ implies $P \approx_1 Q$.*

Proof: We show that the relation

$$\mathcal{S} = \{(P, Q) : P, Q \in L\pi \text{ and } p \notin \text{fn}(P, Q) \text{ and } (p \triangleright b \mid P) \approx_1 (p \triangleright b \mid Q)\}$$

is a link bisimulation up to structural congruence. The proof is straightforward and it is based on the fact that p is a fresh name and therefore there cannot be any interaction between the link $p \triangleright b$ and the processes P and Q . □

Lemma A.5 *Let P and Q be two $L\pi$ -processes and b a name such that $b \notin \text{fn}(P, Q)$. Then $P \approx_{\text{lut}} Q$ implies $P \mid \overline{a}b \approx_{\text{lut}} Q \mid \overline{a}b$.*

Proof: We show that the relation

$$\mathcal{S} = \{(P \mid \overline{a}b, Q \mid \overline{a}b) : P, Q \in L\pi, b \notin \text{fn}(P, Q), P \approx_{\text{lut}} Q\} \cup \approx_{\text{lut}}$$

is a link bisimulation up to link up to \equiv . It is enough to consider two cases:

1. $P \mid \overline{a}b \xrightarrow{\alpha} P' \mid \overline{a}b$, that is, $P \xrightarrow{\alpha} P'$. Then the process $Q \mid \overline{a}b$ can match this actions in the same way.
2. $P \mid \overline{a}b \xrightarrow{\alpha} P''$, that is, the output particle $\overline{a}b$ is consumed. Then there are two possibilities:
 - (a) $P \mid \overline{a}b \xrightarrow{\overline{a}b} P$. Then the process $Q \mid \overline{a}b$ can match this actions in the same way.
 - (b) $P \mid \overline{a}b \xrightarrow{\tau} P'$. This means that $P \xrightarrow{a(b)} P'$. Since $P \approx_{\text{lut}} Q$ we have two cases.
 - i. $Q \xrightarrow{a(b)} Q'$ and $P' \approx_{\text{lut}} Q'$ and the process $Q \mid \overline{a}b$ can match this actions in the same way, or
 - ii. $Q \Longrightarrow Q'$ and $P' \approx_{\text{lut}} Q' \mid \overline{a}b$. Then $Q \mid \overline{a}b \Longrightarrow Q' \mid \overline{a}b$ and since $P' \approx_{\text{lut}} Q' \mid \overline{a}b$ we can conclude that $(P', Q' \mid \overline{a}b) \in \mathcal{S}$.

□

The following lemma shows that \approx_{lut} is preserved by the introduction of links.

Lemma A.6 *Let P and Q be two $L\pi$ -processes and p a name such that $p \notin \text{fn}(P, Q)$. Then*

1. $P \approx_{\text{lut}} Q$ implies $(p \triangleright b \mid P) \approx_{\text{lut}} (p \triangleright b \mid Q)$.
2. $P \approx_{\text{lut}} Q$ implies $(\nu c)(p \triangleright c \mid P) \approx_{\text{lut}} (\nu c)(p \triangleright c \mid Q)$.
3. $P\{p/c\} \approx_{\text{lut}} (\nu c)(p \triangleright c \mid Q)$ implies $(\nu c)(p \triangleright c \mid P) \approx_{\text{lut}} (\nu c)(p \triangleright c \mid Q)$.
4. $P\{p/c\} \approx_{\text{lut}} (p \triangleright b \mid Q)$, $c \notin \text{fn}(Q)$, implies $(\nu c)(p \triangleright c \mid P) \approx_{\text{lut}} (p \triangleright b \mid Q)$.

Proof: 1. It suffices to show that the relation

$$\mathcal{S} = \{(p \triangleright b \mid P, p \triangleright b \mid Q) : P, Q \in L\pi, P \approx_{\text{lut}} Q, p \notin \text{fn}(P, Q)\}$$

is a link bisimulation up to link up to \equiv . Since $p \notin \text{fn}(P, Q)$ there cannot be an interaction between the link and the processes. The most interesting case is when $p \triangleright b \mid P \xrightarrow{p(w)} p \triangleright b \mid \bar{p}w \mid P$, with w fresh, and $p \triangleright b \mid Q \xrightarrow{p(w)} p \triangleright b \mid \bar{p}w \mid Q$. By Lemma A.5 we conclude that $((p \triangleright b \mid \bar{p}w \mid P), (p \triangleright b \mid \bar{p}w \mid Q)) \in \mathcal{S}$.

2. We prove that the relation

$$\mathcal{S} = \{((\nu c)(p \triangleright c \mid P), (\nu c)(p \triangleright c \mid Q)) : P \approx_{\text{lut}} Q, p \notin \text{fn}(P \mid Q)\}$$

is a link bisimulation up to link up to \equiv . We use the following abbreviation: $A = (\nu c)(p \triangleright c \mid P)$ and $B = (\nu c)(p \triangleright c \mid Q)$. We consider the possible actions of A .

- (a) If $A \xrightarrow{\tau} A_1$, since $p \notin \text{fn}(P, Q)$, there exists P' such that $P \xrightarrow{\tau} P'$ and $A_1 = (\nu c)(p \triangleright c \mid P')$. Since $P \approx_{\text{lut}} Q$ there exists Q' such that $Q \Longrightarrow Q'$ and $P' \approx_1 Q'$. This means that there exists B_1 such that $B \Longrightarrow B_1$, $B_1 = (\nu c)(p \triangleright c \mid Q')$ and $(A_1, B_1) \in \mathcal{S}$.
- (b) If $A \xrightarrow{a(b)} A_1$, with $a \neq c$ and $b \notin \text{fn}(A, B)$. There are two cases:
 - i. $a \neq p$. This means that $P \xrightarrow{a(b)} P'$ and $A_1 = (\nu c)(p \triangleright c \mid P')$. Since $P \approx_{\text{lut}} Q$ there are two possibilities:
 - A. $Q \xrightarrow{a(b)} Q'$ and $P' \approx_{\text{lut}} Q'$. In this case $B \xrightarrow{a(b)} B_1$ where $B_1 = (\nu c)(p \triangleright c \mid Q')$ and $(A_1, B_1) \in \mathcal{S}$.
 - B. $Q \Longrightarrow Q'$ and $P' \approx_{\text{lut}} Q' \mid \bar{a}b$. In this case $B \Longrightarrow B_1 = (\nu c)(p \triangleright c \mid Q')$ with $A_1 \mathcal{S} (\nu c)(p \triangleright c \mid (Q' \mid \bar{a}b)) \equiv B_1 \mid \bar{a}b$.
 - ii. $a = p$. Since $p \notin \text{fn}(P \mid Q)$, it holds that $A_1 = (\nu c)(p \triangleright c \mid \bar{c}b \mid P)$. So, $B \xrightarrow{a(b)} B_1 = (\nu c)(p \triangleright c \mid \bar{c}b \mid Q)$. Since $P \approx_{\text{lut}} Q$ and $b \notin \text{fn}(P, Q)$, by Lemma A.5, we have $(P \mid \bar{c}b) \approx_{\text{lut}} (Q \mid \bar{c}b)$. We conclude that $A_1 \equiv (\nu c)(p \triangleright c \mid P \mid \bar{c}b) \mathcal{S} (\nu c)(p \triangleright c \mid Q \mid \bar{c}b) \equiv B_1$.
- (c) If $A \xrightarrow{\bar{a}b} A_1$. This means that $P \xrightarrow{\bar{a}b} P'$, $\{a, b\} \cap \{c, p\} = \emptyset$ and $A_1 = (\nu c)(p \triangleright c \mid P')$. Since $P \approx_{\text{lut}} Q$, there are three possibilities:
 - i. $Q \xrightarrow{\bar{a}b} Q'$ and $P' \approx_{\text{lut}} Q'$. This implies $B \xrightarrow{\bar{a}b} B_1 = (\nu c)(p \triangleright c \mid Q')$ and $(A_1, B_1) \in \mathcal{S}$.
 - ii. $Q \xrightarrow{\bar{a}(d)} Q'$ with $d \notin \text{fn}(P \mid Q)$. We have two possible requirements for the derivatives. We consider the most difficult, that is, $(w \triangleright b \mid P') \approx_{\text{lut}} (\nu d)(w \triangleright d \mid Q')$ for some fresh name w . We have,

$$B \xrightarrow{\bar{a}(d)} B_1 = (\nu c)(p \triangleright c \mid Q')$$

and

$$\begin{aligned} (w \triangleright b \mid A_1) &\equiv \\ (\nu c)(p \triangleright c \mid (w \triangleright b \mid P')) &\mathcal{S} \\ (\nu c)(p \triangleright c \mid ((\nu d)(w \triangleright d \mid Q'))) &\equiv \\ (\nu d)(w \triangleright d \mid B_1). & \end{aligned}$$

iii. $Q \xrightarrow{\bar{a}h} Q'$, with $h \neq b$ and $(w \triangleright b \mid P') \mathcal{S} (w \triangleright h \mid Q')$ for some fresh name w . We reason as in the previous case.

(d) If $A \xrightarrow{\bar{a}(b)} A_1$ the reasoning is similar to that for case 3.

3. The proof follows from Lemma A.6(2) and Proposition 4.3. Let r be a fresh name, by hypothesis we know that $P\{r/c\} \approx_{\text{lut}} (\nu c)(r \triangleright c \mid Q)$. By Lemma A.6(2), we have

$$(\nu r)(p \triangleright r \mid P\{r/c\}) \approx_{\text{lut}} (\nu r)(p \triangleright r \mid (\nu c)(r \triangleright c \mid Q))$$

for p fresh. By Proposition 4.3 we have

$$(\nu r)(p \triangleright r \mid (\nu c)(r \triangleright c \mid Q)) \equiv (\nu c)((\nu r)(p \triangleright r \mid r \triangleright c) \mid Q) \gtrsim (\nu c)(p \triangleright c \mid Q).$$

Since $(\nu c)(p \triangleright c \mid P) \equiv (\nu r)(p \triangleright r \mid P\{r/c\})$ and $\equiv \approx_{\text{lut}} \equiv \gtrsim \subset \approx_{\text{lut}}$ we can conclude that $(\nu c)(p \triangleright c \mid P) \approx_{\text{lut}} (\nu c)(p \triangleright c \mid Q)$.

4. As in Part 3, the proof can be derived by Lemma A.6(2) and Proposition 4.3.

□

A.5 Proof of Lemma 9.6

We restate Lemma 9.6.

Lemma A.7 (Operational correspondence of $\{\llbracket \cdot \rrbracket\}$) *Let P be a process in $\text{DL}\pi$.*

1. *Suppose that $P \xrightarrow{\mu} P'$. Then we have:*

- (a) *if $\mu = a(b)$ then $\{\llbracket P \rrbracket\} \xrightarrow{a(b')} \gtrsim \{\llbracket P' \rrbracket\}\{b'/b\}$ and $b' \notin \text{fn}(P)$*
- (b) *if $\mu = \bar{a}b$ then $\{\llbracket P \rrbracket\} \xrightarrow{(\nu c)\bar{a}c} \gtrsim_a (c \rightarrow b \mid \{\llbracket P' \rrbracket\})$, with $c \notin \text{fn}(P)$*
- (c) *if $\mu = (\nu b)\bar{a}b$ then $\{\llbracket P \rrbracket\} \xrightarrow{(\nu c)\bar{a}c} \gtrsim_a (\nu b)(c \rightarrow b \mid \{\llbracket P' \rrbracket\})$, with $c \notin \text{fn}(P)$*
- (d) *if $\mu = d(b)\bar{a}b$ then $\{\llbracket P \rrbracket\} \xrightarrow{(\nu c)\bar{a}c} \gtrsim_a (\nu b)(d(b').b \rightarrow b' \mid c \rightarrow b \mid \{\llbracket P' \rrbracket\})$, with $\{b', c\} \cap \text{fn}(P) = \emptyset$*
- (e) *if $\mu = (\nu d)d(b)\bar{a}b$ then $\{\llbracket P \rrbracket\} \xrightarrow{(\nu c)\bar{a}c} \gtrsim_a (\nu b)(\nu d)(d(b').b \rightarrow b' \mid c \rightarrow b \mid \{\llbracket P' \rrbracket\})$, with $\{b', c\} \cap \text{fn}(P) = \emptyset$*
- (f) *if $\mu = \tau$ then $\{\llbracket P \rrbracket\} \xrightarrow{\tau} \gtrsim_a \{\llbracket P' \rrbracket\}$.*

2. *Suppose that $\{\llbracket P \rrbracket\} \xrightarrow{\mu} P_1$. Then there exists $P' \in \text{DL}\pi$ such that:*

- (a) *if $\mu = a(b)$ then $P \xrightarrow{a(b)} P'$ and $P_1 \gtrsim_a \{\llbracket P' \rrbracket\}\{b'/b\}$*
- (b) *if $\mu = (\nu c)\bar{a}c$ then:*
 - i. *either $P \xrightarrow{\bar{a}b} P'$ and $P_1 \gtrsim_a (c \rightarrow b \mid \{\llbracket P' \rrbracket\})$, with $c \notin \text{fn}(P)$*
 - ii. *or $P \xrightarrow{(\nu b)\bar{a}b} P'$ and $P_1 \gtrsim_a (\nu b)(c \rightarrow b \mid \{\llbracket P' \rrbracket\})$, with $c \notin \text{fn}(P)$*

- iii. or $P \xrightarrow{d(b)\bar{a}b} P'$ and $P_1 \succ_a (\nu b)(d(b'). b \rightarrow b' \mid c \rightarrow b \mid \{\!\{P'\}\!\})$,
with $\{b', c\} \cap \text{fn}(P) = \emptyset$
- iv. or $P \xrightarrow{(\nu d)d(b)\bar{a}b} P'$ and $P_1 \succ_a (\nu b)(\nu d)(d(b'). b \rightarrow b' \mid c \rightarrow b \mid \{\!\{P'\}\!\})$,
with $\{b', c\} \cap \text{fn}(P) = \emptyset$
- (c) if $\mu = \tau$ then $P \xrightarrow{\tau} P'$ with $P_1 \succ_a \{\!\{P'\}\!\}$.

Proof: The proof is by transition induction. We prove Part 1. The proof of Part 2 is similar.

1. $\mu = a(b)$. The interesting case is when the last rule applied to get $P \xrightarrow{a(b)} P'$ is **d-in**. By Lemma 5.2(1), since \succ implies \succ_a , it holds that

$$\{\!\{a(b)P\}\!\} = (\nu b)(a(b'). b \rightarrow b' \mid \{\!\{P\}\!\})$$

and

$$(\nu b)(a(b'). b \rightarrow b' \mid \{\!\{P\}\!\}) \xrightarrow{a(b')} (\nu b)(b \rightarrow b' \mid \{\!\{P\}\!\}) \succ_a \{\!\{P\}\!\}\{b'/b\}.$$

2. $\mu = \bar{a}b$. Straightforward.
3. $\mu = (\nu b)\bar{a}b$. Straightforward.
4. $\mu = d(b)\bar{a}b$. The interesting case is when P' is derived by applying rule **o-in**. The result follows from the definition of the encoding.
5. $\mu = (\nu d)d(b)\bar{a}b$. The only significant case is when the last rule applied to get P' is **o- ν** . As in the previous case, the result follows from the definition of the encoding.
6. $\mu = \tau$. The interesting cases are when P' is derived by applying one of the rules **com**, **s-com**, **cls**, or **s-cls**. We consider each of these below.

- (a) Suppose **com** is the last rule applied for deriving $P \xrightarrow{\tau} P'$.

$$\text{com: } \frac{P \xrightarrow{\bar{a}b} P' \quad Q \xrightarrow{a(x)} Q'}{P \mid Q \xrightarrow{\tau} P' \mid Q'\{b/x\}}$$

By induction hypothesis we have:

- $\{\!\{P\}\!\} \xrightarrow{(\nu c)\bar{a}c} \succ_a c \rightarrow b \mid \{\!\{P'\}\!\}$
- $\{\!\{Q\}\!\} \xrightarrow{a(c)} \succ_a \{\!\{Q'\}\!\}\{c/x\}$

with $c \notin \text{fn}(P)$. By Lemma 5.2 we have:

$$\begin{aligned} \{\!\{P \mid Q\}\!\} &= \{\!\{P\}\!\} \mid \{\!\{Q\}\!\} \xrightarrow{\tau} \succ_a (\nu c)(c \rightarrow b \mid \{\!\{P'\}\!\} \mid \{\!\{Q'\}\!\}\{c/x\}) \\ &\quad \succ_a \{\!\{P'\}\!\} \mid \{\!\{Q'\}\!\}\{b/x\} \\ &= \{\!\{P' \mid Q'\{b/x\}\}\!\}. \end{aligned}$$

- (b) Suppose **s-com** is the last rule applied for deriving $P \xrightarrow{\tau} P'$.

$$\text{s-com: } \frac{P \xrightarrow{\bar{a}c} P'}{a(b)P \xrightarrow{\tau} (\nu b)(P'\{c/b\})}.$$

There are two possibilities: either $c \neq b$ or $c = b$.

i. If $c \neq b$ then $(\nu b)(P'\{c/b\}) = P'\{c/b\}$. By induction hypothesis it holds that

$$\{\!\{ P \}\!\} \xrightarrow{(\nu d)\bar{a}d} \succ_a d \rightarrow c \mid \{\!\{ P' \}\!\}$$

with d fresh. Since $\{\!\{ a(b)P \}\!\} \stackrel{\text{def}}{=} (\nu b)(a(b'). b \rightarrow b' \mid \{\!\{ P \}\!\})$, by Proposition 4.3(2) and Lemma 5.2 it holds that:

$$\begin{aligned} \{\!\{ a(b)P \}\!\} &\xrightarrow{\tau} \succ_a (\nu b)((\nu d)(b \rightarrow d \mid d \rightarrow c) \mid \{\!\{ P' \}\!\}) \\ &\succ_a (\nu b)(b \rightarrow c \mid \{\!\{ P' \}\!\}) \\ &\succ_a \{\!\{ P' \}\!\}\{c/b\} \\ &= \{\!\{ P'\{c/b\} \}\!\}. \end{aligned}$$

ii. If $c = b$ then $(\nu b)(P'\{c/b\}) = (\nu b)P'$. By induction hypothesis it holds that

$$\{\!\{ P \}\!\} \xrightarrow{(\nu d)\bar{a}d} \succ_a d \rightarrow c \mid \{\!\{ P' \}\!\}$$

with d fresh. Since $\{\!\{ a(b)P \}\!\} \stackrel{\text{def}}{=} (\nu b)(a(b'). b \rightarrow b' \mid \{\!\{ P \}\!\})$, by Proposition 4.3(2) and Lemma 9.5 it holds that:

$$\begin{aligned} \{\!\{ a(b)P \}\!\} &\xrightarrow{\tau} \succ_a (\nu b)((\nu d)(b \rightarrow d \mid d \rightarrow b) \mid \{\!\{ P' \}\!\}) \\ &\succ_a (\nu b)(b \rightarrow b \mid \{\!\{ P' \}\!\}) \\ &\succ_a (\nu b)\{\!\{ P' \}\!\}. \end{aligned}$$

(c) Suppose **c1s** is the last rule applied for deriving $P \xrightarrow{\tau} P'$.

$$\text{c1s: } \frac{P \xrightarrow{\beta_b \bar{a}b} P' \quad Q \xrightarrow{a(b')} Q' \quad \text{bn}(\beta_b) \cap \text{fn}(Q) = \emptyset}{P \mid Q \xrightarrow{\tau} \beta_b(P' \mid Q'\{b/b'\})}$$

We can suppose $\beta_b = d(b)$ for some d . The case when $\beta_b = (\nu d)d(b)$ is similar. By induction hypothesis it holds that:

- $\{\!\{ P \}\!\} \xrightarrow{(\nu c)\bar{a}c} \succ_a (\nu b)(d(b'). b \rightarrow b' \mid c \rightarrow b \mid \{\!\{ P' \}\!\})$, with $\{b', c\} \cap \text{fn}(P) = \emptyset$.
- $\{\!\{ Q \}\!\} \xrightarrow{a(c)} \succ_a \{\!\{ Q' \}\!\}\{c/b'\}$.

We recall that $\{\!\{ P \mid Q \}\!\} = \{\!\{ P \}\!\} \mid \{\!\{ Q \}\!\}$. Then, by Lemma 5.2, we have:

$$\begin{aligned} \{\!\{ P \}\!\} \mid \{\!\{ Q \}\!\} &\xrightarrow{\tau} \succ_a (\nu c)(\nu b)(d(b'). b \rightarrow b' \mid c \rightarrow b \mid \{\!\{ P' \}\!\} \mid \{\!\{ Q' \}\!\}\{c/b'\}) \\ &\equiv (\nu b)(d(b'). b \rightarrow b' \mid (\nu c)(c \rightarrow b \mid \{\!\{ P' \}\!\} \mid \{\!\{ Q' \}\!\}\{c/b'\})) \\ &\succ_a (\nu b)(d(b'). b \rightarrow b' \mid \{\!\{ P' \}\!\} \mid \{\!\{ Q' \}\!\}\{b/b'\}) \\ &= \{\!\{ d(b)(\{\!\{ P' \}\!\} \mid \{\!\{ Q' \}\!\}\{b/b'\}) \}\!\}. \end{aligned}$$

(d) Suppose **s-c1s** is the last rule applied for deriving $P \xrightarrow{\tau} P'$.

$$\text{s-c1s: } \frac{P \xrightarrow{\beta_c \bar{a}c} P' \quad b \notin \text{n}(\beta_c \bar{a}c)}{a(b)P \xrightarrow{\tau} \beta_c(P'\{c/b\})}$$

We can suppose $\beta_c = d(c)$ for some d . The case when $\beta_c = (\nu d)d(c)$ is similar. By induction hypothesis it holds that:

$$\{\!\{ P \}\!\} \xrightarrow{(\nu h)\bar{a}h} \succ_a (\nu c)(d(c'). c \rightarrow c' \mid h \rightarrow c \mid \{\!\{ P' \}\!\})$$

with $\{c', h\} \cap \text{fn}(P) = \emptyset$.

Since $\{\!\{ a(b)P \}\!\} \stackrel{\text{def}}{=} (\nu b)(a(b'). b \rightarrow b' \mid \{\!\{ P \}\!\})$, by Proposition 4.3 and Lemma 5.2 we have:

$$\begin{aligned} \{\!\{ a(b)P \}\!\} &\xrightarrow{\tau} \succ_a (\nu h)(\nu b)(b \rightarrow h \mid d(c'). c \rightarrow c' \mid h \rightarrow c \mid \{\!\{ P' \}\!\}) \\ &\equiv (\nu b)((\nu h)(b \rightarrow h \mid h \rightarrow c) \mid d(c'). c \rightarrow c' \mid \{\!\{ P' \}\!\}) \\ &\succ_a (\nu b)(b \rightarrow c \mid d(c'). c \rightarrow c' \mid \{\!\{ P' \}\!\}) \\ &\succ_a d(c'). c \rightarrow c' \mid \{\!\{ P' \}\!\}\{c/b\} \\ &= \{\!\{ d(c)P'\{c/b\} \}\!\}. \end{aligned}$$
